**Abstract:** In this paper, we prove the following form of Stone's representation theorem: Let  $\mathcal{A}$  be a  $\sigma$ -algebra of subsets of a set  $X$ . Then there exists a totally disconnected compact Hausdorff space  $\mathcal{K}$  for which  $(\mathcal{A}, \cup, \cap)$  and  $(\mathcal{C}(\mathcal{K}), \cup, \cap)$ , where  $\mathcal{C}(\mathcal{K})$  denotes the set of all clopen subsets of  $\mathcal{K}$ , are isomorphic as Boolean algebras. Furthermore, by defining appropriate joins and meets of countable families in  $\mathcal{C}(\mathcal{K})$ , we show that such an isomorphism preserves  $\sigma$ -completeness. Then, as a consequence of this result, we obtain the result that if  $ba(X, \mathcal{A})$  (respectively,  $ca(X, \mathcal{A})$ ) denotes the Banach space (under the variation norm) of all bounded, finitely additive (respectively, all countably additive) complex-valued set functions on  $(X, \mathcal{A})$ , then  $ca(X, \mathcal{A}) = ba(X, \mathcal{A})$  if and only if (1)  $\mathcal{C}(\mathcal{K})$  is  $\sigma$ -complete; and if and only if (2)  $\mathcal{A}$  is finite. We also give another application of these results.

**Key Words:** Boolean ring, Boolean space, Stone space, Stone representation, bounded finitely additive set function, countably additive set function, convergence of sequences of measures, weak topology.
