Detecting ends of residually finite groups in profinite completions

Owen Cotton-Barratt

(Submitted on 1 May 2012)

Let \mathcal{C} be a variety of finite groups. We use profinite Bass-Serre theory to show that if $\mathcal{H} \twoheadrightarrow G$ is a map of finitely generated residually \mathcal{C} groups such that the induced map $\hat{\mathcal{H}} \rightarrow \hat{G}$ is a surjection of the pro- \mathcal{C} completions, and G has more than one end, then H has the same number of ends as G . However if G has one end the number of ends of H may be larger; we observe cases where this occurs for \mathcal{C} the class of finite p -groups.

We produce a monomorphism of groups $\mathcal{H} \twoheadrightarrow G$ such that: either G is hyperbolic but not residually finite; or $\hat{\mathcal{H}} \rightarrow \hat{G}$ is an isomorphism of profinite completions but H has property (T) (and hence (FA)), but G has neither. Either possibility would give new examples of pathological finitely generated groups.
