**Abstract:** Let  $\mathcal{G}(v, e)$  be the set of all simple graphs with  $v$  vertices and  $e$  edges and let  $P_2(G) = \sum d_i^2$  denote the sum of the squares of the degrees,  $d_1, \dots, d_v$ , of the vertices of  $G$ .

It is known that the maximum value of  $P_2(G)$  for  $G \in \mathcal{G}(v, e)$  occurs at one or both of two special graphs in  $\mathcal{G}(v, e)$ --the quasi-star graph or the quasi-complete graph. For each pair  $(v, e)$ , we determine which of these two graphs has the larger value of  $P_2(G)$ . We also determine all pairs  $(v, e)$  for which the values of  $P_2(G)$  are the same for the quasi-star and the quasi-complete graph. In addition to the quasi-star and quasi-complete graphs, we find all other graphs in  $\mathcal{G}(v, e)$  for which the maximum value of  $P_2(G)$  is attained. Density questions posed by previous authors are examined.
