(Submitted on 16 Jul 2011)

Efficient link scheduling in a wireless network is challenging. Typical optimal algorithms require solving an NP-hard sub-problem. To meet the challenge, one stream of research focuses on finding simpler sub-optimal algorithms that have low complexity but high efficiency in practice. In this paper, we study the performance guarantee of one such scheduling algorithm, the Longest-Queue-First (LQF) algorithm. It is known that the LQF algorithm achieves the full capacity region,  $\Lambda$ , when the interference graph satisfies the so-called local pooling condition. For a general graph  $G$ , LQF achieves (i.e., stabilizes) a part of the capacity region,  $\sigma^*(G) \Lambda$ , where  $\sigma^*(G)$  is the overall local pooling factor of the interference graph  $G$  and  $\sigma^*(G) \leq 1$ . It has been shown later that LQF achieves a larger rate region,  $\Sigma^*(G) \Lambda$ , where  $\Sigma^*(G)$  is a diagonal matrix. The contribution of this paper is to describe three new achievable rate regions, which are larger than the previously-known regions. In particular, the new regions include all the extreme points of the capacity region and are not convex in general. We also discover a counter-intuitive phenomenon in which increasing the arrival rate may sometime help to stabilize the network. This phenomenon can be well explained using the theory developed in the paper.
