**摘要** Let an  $n \times m$  matrix of observations,  $Y$ , have distribution  $N(XB, G \oplus V)$ , where  $X, G > 0$  and  $V > 0$  are known  $n \times p$ ,  $n \times n$  and  $m \times m$  matrices respectively,  $B$  is an unknown  $p \times m$  matrix of parameters. We consider the problem of estimating the loss  $L = (S\bar{B} - SXB)C(S\bar{B} - SXB)'$ , where  $S$  and  $C > 0$  are known  $t \times n$  and  $m \times m$  matrices respectively  $\bar{B} = (X'G^{-1}X)^{-1}X'G^{-1}y$ . It is proved that the uniformly minimum risk unbiased estimator of  $L$ ,  $\bar{L}_0 = (\text{tr } CV)SX(X'G^{-1}X)^{-1}X'S$ , is admissible for  $q = \text{rank } SX = 1$  and  $m \leq 4$ , or for  $q \geq 2$  and  $m \leq 2$  and inadmissible for  $m \geq 5$  with matrix loss function. It is also shown that the above  $\bar{L}_0$  is a  $\Gamma$ -minimax estimator of  $L$  against a class of priors.
