(Submitted on 9 Jun 2011)

Four previously known rotational bands in  $^{76}\text{Rb}$  have been extended to moderate spins using the Gammasphere and Microball gamma ray and charged particle detector arrays and the  $^{40}\text{Ca}(^{40}\text{Ca},3\text{pn})$  reaction at a beam energy of 165 MeV. The properties of two of the negative-parity bands can only readily be interpreted in terms of the highly successful Cranked Nilsson-Strutinsky model calculations if they have the same configuration in terms of the number of  $g_{9/2}$  particles, but they result from different nuclear shapes (one near-oblate and the other near-prolate). These data appear to constitute a unique example of shape co-existing structures at medium spins.

Comments: Accepted for publication in Physics Letters B
