摘要: 受青藏高原和印度洋暖湿气流的影响,西藏东南部分布着我国面积最大的海洋性冰川,这些海洋性冰川的长期运动产生了数量惊人的冰碛物,成为泥石流发育最重要的物源。多年来,西藏东南部的冰川泥石流频繁爆发,严重危及当地居民的生命财产、进藏交通系统的建设以及国际河流的安全。林芝地区波密县一直是区域冰川泥石流活动的中心,以2007年9月初波密县发生的几场泥石流为研究对象,结合波密气象站的气象数据,重点分析了前期气温和降水两个气象因子在该次群发性泥石流中的作用,构建了此次冰川泥石流暴发的前期水热条件,并以“9·4”松绕天摩沟泥石流为重点研究对象,分析了其形成机制。

Abstract: Affected by the Tibet Plateau and the warm-moist air current from the Indian Ocean, there exists the largest area of maritime glacier in the Southeast Tibet, China. Movement of the glacier in the past long time had triggered incredible amount of debris, which is the primary source material for debris flows. In the past years, glacier debris flows broke out frequently, posing a threatening to the local people, traffic facilities and trans-border rivers. In particular, Bomi County, Linzhi Prefecture in the southeast Tibet has been the center of glacier debris

flows activities. This paper chooses several successive debris flows occurred at the beginning of September 2007 as the research object, and uses the meteorological data from Bomi Meteorological Station, to analyze the effectiveness of antecedent temperatures and rainfalls of the successive debris flows, and formulate its pre-hydrothermal condition. Then, the 9.4 Tianmo debris flows is chosen to disclose its triggering mechanism.
