Geostatistical prediction of clay percentage based on soil survey data

Keywords precision farming, geostatistics, statistical methods, kriging, sampling, spatial variation,

Abstract

In precision farming fields may be divided into management zones according to the spatial variation in soil properties. Clay content is an important soil characteristic, because it is associated with other soil properties that are important in management. Soil survey data from 218 sampling sites taken from an area of 218 ha were used to predict the spatial variation of clay percentage geostatistically in a soil in Jokioinen, Finland. The exponential and spherical models with a nugget component were fitted to the experimental variogram. Results indicated that the medium-range pattern could be modelled, but the short-range variation could not, due to sparsity of sample points at short distances. The effect of sampling density on the kriging error was evaluated using the random simulation method. Kriging with the spherical model produced a map with smooth variation in clay percentage. The standard error of kriging estimates decreased only slightly as the density of samples was increased. The predictions were divided into three classes based on the clay percentage. Areas with clay content less than 30%, between 30% and 60% and over 60% belong to non-clay, clay and heavy clay zones, respectively. With additional information from soil samples on the contents of nutrients and organic matter these areas can serve as agricultural management zones.
