## Cryptography for Efficiency: Authenticated Data Structures Based on Lattices and Parallel Online Memory Checking

## Charalampos Papamanthou and Roberto Tamassia

Abstract: In this work, we initially design a new authenticated data structure for a  $\left\{ present the first dynamic authenticated table that is <math>\left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ present the first dynamic authenticated table that is \left\{ previous constructions, such as the Merkle tree. Moreover, the space complexity of our authenticated data structure is $O(n)$ and logarithmic bounds hold for other performance measures, such as proof complexity (number of group elements contained in the proof). To achieve this result, we establish and exploit a property that we call <math>\left| prepeted linearity \right|$  of lattice-based hash functions and show how the security of lattice-based digests can be guaranteed under updates. An one-time preprocessing stage of  $O(n \log n)$  complexity is also required at setup. This is the first construction achieving a constant update bound without causing other complexities to increase beyond logarithmic. All previous solutions enjoying such a complexity bound for updates enforce O(present) proof or query complexity. As an application, we provide the first construction of an aut

We secondly observe that the repeated linearity of the used lattice-based cryptographic primitive lends itself to a natural notion of parallelism: As such, we describe  $\left[ \left[ \operatorname{parallel} \right] \right]$  versions of our authenticated data structure algorithms, yielding the first parallel  $\left[ \operatorname{parallel} \right]$  versions of our authenticated data structure algorithms, yielding the first parallel  $\left[ \operatorname{parallel} \right]$  versions of our authenticated data structure algorithms, yielding the first parallel  $\left[ \operatorname{parallel} \right]$  versions of our authenticated data structure algorithms, yielding the first parallel  $\left[ \operatorname{parallel} \right]$  versions of our authenticated data structure algorithms, yielding the first parallel as secret key setting, i.e., there is only need for small  $\left[ \operatorname{parallel} \right]$  but not  $\left[ \operatorname{parallel} \right]$  memory. We base the security of our constructions on the difficulty of approximating the gap version of the shortest vector problem in lattices ( $\left[\operatorname{parallel} \right]$ ) within polynomial factors.

Category / Keywords: authenticated data structures, lattice-based cryptography, memory checking
