**Abstract** Gas-liquid (G-L) and liquid-solid (L-S) mass transfer coefficients were characterized in a gas-liquid-solid (G-L-S) three-phase magnetically stabilized bed (MSB) using amorphous alloy SRNA-4 as the solid phase. Effects such as superficial liquid velocity, superficial gas velocity, magnetic strength, liquid viscosity, and particle size were investigated. Experimental results indicated that the G-L volumetric mass transfer coefficients ( $K_La$ ) increased along with the magnetic strength, superficial gas and liquid velocities. Proper increase of liquid viscosity promoted  $K_La$  only in the range of lower liquid viscosity. The external magnetic field made L-S mass transfer coefficients ( $K_s$ ) in the G-L-S MSB lower than those of conventional fluidized beds.  $K_s$  in the MSB almost kept constant as the superficial liquid velocity and superficial gas velocity increased and decreased with the liquid viscosity and surface tension, while increased with the particle size.  $K_s$  showed uniform axial and radial distributions except of small decreases close to the wall. Dimensionless correlations were established to estimate  $K_La$  and  $K_s$  of the MSB with SRNA-4 catalysts, which showed the average error of 5.4% and 2.5% respectively.

**Keywords** magnetically stabilized bed, gas-liquid mass transfer, liquid-solid mass transfer, SRNA-4 catalyst

### 1 INTRODUCTION

Magnetically stabilized beds (MSB) exhibit an unique combination of packed-bed and fluidized-bed properties. Gas-liquid-solid (G-L-S) three-phase MSB has recently attracted more attention in the field of biotechnology processes (such as bioseparation or immobilized enzyme systems) and chemical engineering (such as the hydrogenation reaction system). The interphase mass transfer behavior plays an important role in the optimal operation of practical MSB. However, many reports indicate that both the gas-liquid (G-L) mass transfer coefficients ( $K_La$ ) and the liquid-solid (L-S) mass transfer coefficient ( $K_s$ ) are greatly influenced by the operation system in the MSB.

In the case of G-L mass transfer, many investigations studied  $K_La$  in the G-L-S MSB with different solid phases. Weng *et al.*<sup>[1]</sup> reported that the increase of magnetic strength enhanced  $K_La$  and established the G-L mass transfer models for three-phase MSB reactors using magnetic alginate particles as the solid. Thompson and Worden<sup>[2]</sup> studied a three-phase fluidized bed equipped with an axial magnetic field and concluded that  $K_La$  maintained the same value or decreases as the magnetic field increased. Al-Qodah and Al-Hassan<sup>[3]</sup> studied a three-phase stripper containing magnetic  $Fe_3O_4$  particles under the external radial magnetic field and claimed that  $K_La$  become higher as the gas velocity and the magnetic strength increased, and  $K_La$  showed a linear relationship with the gas velocity at a

constant magnetic strength. Chen and Leu<sup>[4]</sup> investigated the mass transfer of three-phase MSB with Ni powders of 194 $\mu$ m diameter and concluded that  $K_La$  of MSB was enhanced by the magnetic strength and could be increased by 70% at higher magnetic strength, which was close to the mass transfer coefficient of G-L bubbled columns.

On the other hand, there were only few reports with controversial conclusions on the local L-S mass transfer behavior in the G-L-S MSB. Some investigations<sup>[5–8]</sup> suggested that the external magnetic force enhanced the L-S mass transfer, and  $K_s$  increased with the magnetic strength. However, other reports<sup>[9–11]</sup> indicated that the external magnetic field played negative roles in  $K_s$ .

The ferromagnetic catalyst of SRNA-4, an amorphous nickel alloy catalyst, has high hydrogenation activity at low temperature. Meng *et al.*<sup>[12]</sup> has used SRNA-4 in the MSB for purification of caprolactam. So far, no report has been found about the interphase mass transfer characteristic of the G-L-S MSB with commercial magnetic catalyst particles of SRNA-4. In this study,  $K_La$  and  $K_s$  in the G-L-S MSB using amorphous alloy SRNA-4 as the magnetic solid phase are measured and correlated. The results may be valuable to the practical design and optimization of MSB using SRNA-4 as the catalyst.

ratios of a magnetically stabilized bed is shown in Fig.1. The Plexiglas column is 1.5m in height with an i.d. of 0.1m. The axially uniform magnetic field was provided by seven similar DC-powered copper wire coils surrounding the column with 0.16m i.d. and 0.1m in height. All experiments were carried out at  $(25 \pm 1)^\circ\text{C}$ . The liquid flow rate was measured by calibrated rotameters with the precision of 2.5%. As the gas phase, air was introduced into the reactor through an air compressor, the air volumetric flow rate was measured by the rotameter (with the precision of 2.5%). The solid phase was spherical amorphous alloy catalyst SRNA-4<sup>[12]</sup> with the diameter of 80–120 $\mu\text{m}$  and 120–200 $\mu\text{m}$ , the apparent density of 2500 $\text{kg}\cdot\text{m}^{-3}$ . The viscosity of the solution was adjusted within the range of 1–5 $\text{mPa}\cdot\text{s}$  by the adding of sodium carboxymethyl cellulose and measured by a viscometer (NDJ-7, Shanghai Tianping). Surface tension of solutions was adapted to the range of 54–72 $\text{mN}\cdot\text{m}^{-1}$  by the addition of a nonionic surfactant and measured by a tensiometer (XP-2000, ZhongChen).

**Figure 1** Experimental set-up of MSB

1—fluidized bed; 2—field coils; 3—direct power; 4—testing instrument; 5—pressure sensor; 7—air compressor; 8—liquid pump; 9—heater and controller; 10—liquid distributor; 11—gas-liquid distributor; 12—liquid rotameter; 13—liquid tank

Sodium sulfite ( $0.5\text{mol}\cdot\text{L}^{-1}$ ) aqueous solution was used as the liquid phase, which contained  $0.001\text{mol}\cdot\text{L}^{-1}$  cobalt sulfate as the catalyst for the oxidation of sulfite. The overall G-L volumetric mass transfer coefficient,  $K_La$ , is determined by means of the oxidation of sodium sulfite method<sup>[13]</sup>. Oxygen concentration of the gas phase and sodium sulfite concentration of the liquid phase inside the reactor was measured using the titrimetry.

The electrolytic solution was a mixture of  $0.001\text{mol}\cdot\text{L}^{-1}$  potassium ferrocyanide,  $0.001\text{mol}\cdot\text{L}^{-1}$  potassium ferricyanide and  $0.02\text{mol}\cdot\text{L}^{-1}$  sodium hydroxide. Sodium hydroxide was added as the electrolyte support to minimize the migration effects. The

electrochemical method<sup>[14–16]</sup> was used to measure the local L-S mass transfer coefficients ( $K_s$ ) in the MSB.

### 3 RESULTS AND DISCUSSION

#### 3.1 G-L mass transfer behavior

##### 3.1.1 Effects of the magnetic strength on $K_La$

Figure 2 indicated that  $K_La$  increased with the magnetic strength within the experimental range. The average gas holdup was proportional to the magnetic strength, *i.e.*, the higher magnetic strength, the larger average gas holdup  $\varepsilon_g$  (Fig.3). Additionally, it was observed that the size of air bubbles decreased obviously as the magnetic strength increased, which enhanced the interfacial area as well as  $K_La$ .

**Figure 2** Effect of magnetic strength on  $K_La$   
( $\mu=1\text{mPa}\cdot\text{s}$ ,  $d_p=80\text{--}120\mu\text{m}$ ,  $U_l=1.13\text{mm}\cdot\text{s}^{-1}$ )  
 $U_g$ ,  $\text{mm}\cdot\text{s}^{-1}$ :  $\blacklozenge$  1.77;  $\square$  2.83;  $\triangle$  3.54;  $\diamond$  4.25

**Figure 3** Average gas holdup as a function of magnetic strength and gas velocity  
( $\mu=1\text{mPa}\cdot\text{s}$ ,  $d_p=80\text{--}120\mu\text{m}$ ,  $U_l=1.42\text{mm}\cdot\text{s}^{-1}$ )  
 $H$ ,  $\text{kA}\cdot\text{m}^{-1}$ :  $\diamond$  0;  $\square$  1;  $\triangle$  2

##### 3.1.2 Effects of superficial gas velocity on $K_La$

Figure 4 showed the effects of gas velocity on  $K_La$ , which indicated approximately linear relationship between  $K_La$  and the gas velocity within the experimental range of magnetic strength and liquid velocity. It is reasonable because the average gas holdup increases and the average size of air bubbles decreases with the increase of gas velocity, which enhance the interface areas between gas and liquid phase. On the other hand, the higher gas velocity accelerates the rising rate of air bubbles in the bed and promotes the liquid turbulences around air bubbles, which reduce the mass transfer resistance between the liquid film around the bubble surface and the bulky liquid phase, and consequently made  $K_La$  increased.

##### 3.1.3 Effects of superficial liquid velocity on $K_La$

Figure 5 showed that  $K_La$  increased only slightly

**Figure 4** Effect of superficial gas velocity on  $K_{La}$   
( $\mu=1\text{mPa}\cdot\text{s}$ ,  $d_p=80\text{--}120\mu\text{m}$ )

◆  $H=0$ ,  $U_l=1.13\text{mm}\cdot\text{s}^{-1}$ ; ■  $H=2\text{kA}\cdot\text{m}^{-1}$ ,  $U_l=1.13\text{mm}\cdot\text{s}^{-1}$ ;

with the liquid velocity. According to the assumption of Lara-Marquez *et al.*<sup>[17]</sup>, the average diameter of air bubbles is in proportion to turbulent micro-scales. Therefore, the G-L interfacial area increased in strongly turbulent liquid phase and then  $K_{La}$  become larger.

### 3.1.4 Effects of liquid viscosity on $K_{La}$

The higher liquid viscosity facilitated both the increase of air bubble size and the average gas holdup (as shown in Fig.6). These two factors have adverse influences on the G-L interfacial areas. Fig.6 indicated that the average gas holdup has significant effects on the G-L interfacial areas, comparing with those on the average size of air bubbles. Thus,  $K_{La}$  increased with the liquid viscosity in our experimental range ( $\mu < 5\text{mPa}\cdot\text{s}$ ) (as shown in Fig.7). This is consistent with Chen and Leu<sup>[18]</sup> who reported that the  $K_{La}$  value increased at lower liquid viscosity ( $\mu < 5\text{mPa}\cdot\text{s}$ ) while decreased at higher liquid viscosity ( $\mu > 5\text{mPa}\cdot\text{s}$ ) using gas distributors with small pore diameter (0.1mm).

## 3.2 L-S mass transfer behavior

### 3.2.1 Effect of superficial liquid velocity and magnetic strength on $K_s$

Figure 8 indicated that  $K_s$  almost kept unchanged with the liquid velocity. Song<sup>[19]</sup> draw the consistent conclusion in a convention G-L-S three-phase fluidized beds by using benzoic acid miscibility to measure  $K_s$ . As the magnetic strength increased,  $K_s$  in the MSB decreased, which is attributed to the influence of the magnetic field on the particle coalescence. Under higher magnetic strength, singly particles in the fluidized bed gradually transferred into double-, triplet-, or even multi-particle clusters. Consequently the L-S mass transfer resistance became larger and the swaying velocity of solid particles was limited, which resulted in the lower value of  $K_s$ .

**Figure 8** Effect of liquid superficial velocity and magnetic field intensity on  $K_s$

( $\mu=1\text{mPa}\cdot\text{s}$ ,  $\sigma=71.97\text{mN}\cdot\text{m}^{-1}$ ,  $U_g=1.77\text{m}\cdot\text{s}^{-1}$ ,  $d_p=80\text{--}120\mu\text{m}$ )  
 $H$ ,  $\text{kA}\cdot\text{m}^{-1}$ : ◆ 0; ■ 2; ▲ 4

### 3.2.2 Effect of superficial gas velocity on $K_s$

$K_s$  slightly increased with the lower superficial gas velocity, then turned to be constant at higher gas velocity (as shown in Fig.9). At the initial stage of introducing air into the bed, the liquid turbulence is accelerated, however, the full-developed turbulence of the bulky liquid will not obviously change even at higher superficial gas velocity, which resulted in approximately constant value of  $K_s$  at higher gas velocity.

### 3.2.3 Effect of liquid viscosity on $K_s$

Figure 10 indicated that  $K_s$  decreased with the increase of liquid viscosity. As the liquid viscosity increased, the diffusion coefficient become smaller and the diffusion boundary layer become thicker, which made  $K_s$  decreased at higher liquid viscosity.

**Figure 9** Effects of gas superficial velocity on  $K_s$   
 ( $\mu=1\text{mPa}\cdot\text{s}$ ,  $H=4\text{kA}\cdot\text{m}^{-1}$ ,  $d_p=80\text{--}120\mu\text{m}$ ,  $\sigma=71.97\text{mN}\cdot\text{m}^{-1}$ )  
 $U_l, \text{m}\cdot\text{s}^{-1}$ :  $\blacklozenge$  1.33;  $\blacksquare$  1.42;  $\blacktriangle$  1.70

**Figure 12** Effect of particle size on  $K_s$   
 ( $\mu=1\text{mPa}\cdot\text{s}$ ,  $\sigma=71.97\text{mN}\cdot\text{m}^{-1}$ ,  $H=4\text{kA}\cdot\text{m}^{-1}$ ,  $U_l=1.42\text{mm}\cdot\text{s}^{-1}$ )  
 $d_p, \mu\text{m}$ :  $\blacklozenge$  80—120;  $\blacksquare$  120—200

**Figure 10** Effect of liquid viscosity on  $K_s$   
 ( $\sigma=71.97\text{mN}\cdot\text{m}^{-1}$ ,  $H=4\text{kA}\cdot\text{m}^{-1}$ ,  $d_p=80\text{--}120\mu\text{m}$ ,  $U_g=1.77\text{m}\cdot\text{s}^{-1}$ )  
 $\mu, \text{mPa}\cdot\text{s}$ :  $\blacklozenge$  1;  $\blacksquare$  3;  $\blacktriangle$  5

**3.2.4** Effect of liquid surface tension on  $K_s$

As the liquid surface tension decreased,  $K_s$  become larger (Fig.11). The lower liquid surface tension can prevent the air bubbles from coalescence but enhance the gas holdup, so that there appeared much more small air bubbles and the surface renewal frequency was faster than that under higher surface tension. Thus the L-S mass transfer coefficient increased which is accordance to the diffusion theory of Surface Renewal Model.

**Figure 11** Effect of liquid surface tension on  $K_s$   
 ( $\mu=1\text{mPa}\cdot\text{s}$ ,  $\sigma=71.97\text{mN}\cdot\text{m}^{-1}$ ,  $H=4\text{kA}\cdot\text{m}^{-1}$ ,  $d_p=80\text{--}120\mu\text{m}$ ,  
 $U_l=1.42\text{m}\cdot\text{s}^{-1}$ )  
 $\sigma, \text{mN}\cdot\text{m}^{-1}$ :  $\blacklozenge$  71.97;  $\blacksquare$  61.44;  $\blacktriangle$  54.42

**3.2.5** Effect of particle size on  $K_s$

Figure 12 indicated that  $K_s$  with larger particles was higher than that with smaller size particles. In the case of larger particles, the liquid turbulence is stronger than that of smaller particles, which leads to the decrease of the diffusion boundary layer. It is the decreased diffusion boundary layer that results in the higher  $K_s$  with larger particles.

**3.2.6** Radial and axial distributions of  $K_s$

$K_s$  showed similar tendency of its radial distribution under various operating and property parameters. Close to the wall occurred small decrease of  $K_s$ , whereas no variation of  $K_s$  was observed along other radial positions (as shown in Fig.13). Fig.14 indicated that  $K_s$  had a uniform axial distribution in the G-L-S three-phase MSB.

**Figure 13** Radial distributions of  $K_s$   
 $\blacklozenge H=0, \mu=1\text{mPa}\cdot\text{s}, d_p=80\text{--}120\mu\text{m}, \sigma=71.97\text{mN}\cdot\text{m}^{-1}$ ;  
 $\blacksquare H=4\text{kA}\cdot\text{m}^{-1}, \mu=1\text{mPa}\cdot\text{s}, d_p=80\text{--}120\mu\text{m}, \sigma=71.97\text{mN}\cdot\text{m}^{-1}$ ;

**3.3** Correlations for G-L and L-S mass transfer coefficients

Based on the experimental results, it is suggested that the G-L volumetric mass transfer coefficient is the function of magnetic strength, gas and liquid velocity and liquid viscosity in the MSB. The following dimensionless correlation was developed to estimate  $K_L a$  in this type of MSB.

$$Sh_1 = 1.46Re_1^{0.0813}Fr_1^{0.491}Sc^{1.05}Ga^{0.478}\exp(0.183H/H_{\max}) \quad (1)$$

Eq.(1) fits the experimental data well under the measured conditions, *i.e.*, the particle diameter of 80—120 $\mu\text{m}$ ,  $H=0\text{--}8\text{kA}\cdot\text{m}^{-1}$ ,  $U_g=0.6\text{--}4.2\text{mm}\cdot\text{s}^{-1}$ ,  $U_l=1.2\text{--}2.6\text{mm}\cdot\text{s}^{-1}$ , and  $\mu=1\text{--}5\text{mPa}\cdot\text{s}$ . The average error between the calculated and the experimental data is 5.4%.

Combining the effect of magnetic strength with the method of Hassanien<sup>[20]</sup> for L-S mass transfer coefficients, the correlated equation was obtained as below to estimate  $K_s$ .

$$Sh_2 = 0.472Fr_2^{0.00443}Ga^{0.420}Re_2^{-0.0141}Sc^{1/3}\exp(-0.0802H/H_{\max}) \quad (2)$$

Eq.(2) fits the experimental data well under the measured conditions, *i.e.*, the particle diameter of 80—200 $\mu\text{m}$ ,  $H=0\text{--}8\text{kA}\cdot\text{m}^{-1}$ ,  $U_g=0.6\text{--}4.2\text{mm}\cdot\text{s}^{-1}$ ,  $U_l=1.2\text{--}2.6\text{mm}\cdot\text{s}^{-1}$ ,  $\mu=1\text{--}5\text{mPa}\cdot\text{s}$ , and  $\sigma=54\text{--}72\text{mN}\cdot\text{m}^{-1}$ . The average error between the calculated and the experimental data is 2.5%.

#### 4 CONCLUSIONS

Both G-L and L-S mass transfer behavior in G-L-S magnetically stabilized bed were studied under various conditions using amorphous alloy catalysts SRNA-4 as the solid phase. Experimental results indicated that the external magnetic field provided higher G-L volumetric mass transfer coefficients in three-phase MSB, comparing with those in conventional G-L-S fluidized beds.  $K_La$  increased along with the magnetic strength, superficial gas and liquid velocities, besides liquid viscosity with lower values. A correlated equation was established to estimate  $K_La$  of the MSB, and the average error between the estimated and the experimental data was 5.4%.

It was found that L-S mass transfer coefficients in the G-L-S MSB using amorphous alloy catalysts SRNA-4 were lower than those in conventional fluidized beds.  $K_s$  almost kept constant as the superficial liquid velocity and superficial gas velocity increased, whereas decreased with the liquid viscosity and surface tension. However,  $K_s$  increased with the particle size of SRNA-4 catalyst.  $K_s$  showed uniform axial and radial distributions except of slight decrease close to the wall. A correlated equation of  $K_s$  was established in the MSB, and the average estimation error was 2.5%.

## Call for Papers

### The First International Symposium on Sustainable Chemical Product and Process Engineering

The First International Symposium on Sustainable Chemical Product and Process Engineering will be held on Sep.25-28, 2007 in Guangzhou, China. The symposium is co-sponsored by the National Science Foundation of China (NSFC), the USA National Science Foundation (NSF), and South China University of Technology. The symposium focus on (1) Green chemical reaction and catalysis; (2) Renewable resources; (3) Green nanotechnology in material design; (4) Multi-scale property-focused product design; (5) Integration of design and operation of green process systems; (6) Recovery, recycling & re-integration (3R) of chemical products and systems; (7) Life cycle analysis of chemical products/processes. Participants from China and abroad are welcome to attend this symposium.

#### The International Program Committee (IPC) Co-Chairs

Prof. B. Z. Chen            Tsinghua University, China

Prof. E. L. Cussler        Minnesota University, USA

#### The Symposium Co-Chairs

Prof. Y. Qian                South China University of Technology

Prof. Y. L. Huang         Wayne State University, USA

#### Authors' Timetable

Abstract (one page) submission deadline	January 20, 2007
Notification of acceptance of abstract	March 15, 2007
Full paper (6 pages) submission deadline	May 15, 2007
Acceptance notification, pre-registration	July 1, 2007
Symposium registration and Reception	September 25, 2007
Symposium Plenary, sessions, and visiting	September 26-28, 2007

All inquiry and submission refers to the symposium Website: <http://www.scut.edu.cn/gct>
