(Received: August 8, 1997)

**SUMMARY:** Using a semiclassical approach, we have calculated electron-, proton-, and He III-impact line widths and shifts for 4 Si XI and 61 Si XIII multiplets as a function of temperature (500 000 K - 6 000 000 K) and perturber density ( $10^{16} \text{ cm}^{-3}$  -  $10^{23} \text{ cm}^{-3}$ ).

## 1. INTRODUCTION

Due to the high cosmical abundance of silicon, data on its spectral lines, as well as on spectral lines for its various ionization stages are of particular interest for analysis and modelling of stellar plasma. Stark broadening parameters of Si XI and Si XIII spectral lines are obviously of interest not only to astrophysics, as e.g. for the consideration of radiative transfer through subphotospheric layers, but also for the fusion plasmas and laser produced plasmas research. The development of soft x-ray lasers, where Stark broadening data are needed to calculate gain values, model radiation trapping and to consider photoresonant pumping schemes (see e.g. Griem and Moreno, 1990; Fill and Schöning, 1994), additionally increased the interest in such results.

As a continuation of our programme (Dimitrijević, 1996) to obtain as large as possible set of reliable Stark broadening data needed for the consideration and modeling of astrophysical and laboratory plasmas as well as for investigations of laser produced and fusion plasmas, we have calculated within the

semiclassical-perturbation formalism (Sahal–Bréchot, 1969ab, see also Sahal - Bréchot, 1974, Fleurier et al, 1977, Dimitrijević and Sahal - Bréchot, 1984, Dimitrijević et al. 1991, Dimitrijević and Sahal - Bréchot, 1995) electron-, proton-, and He III-impact line widths and shifts for 4 Si XI and 61 Si XIII multiplets. The formalism applied to the problem of Stark broadening of multicharged silicon ion lines, has been reviewed several times, e.g. briefly in Dimitrijević and Sahal - Bréchot, 1995.

## 2. RESULTS AND DISCUSSION

Details of the calculation procedure as well as the complete analysis of the results obtained, will be published in Dimitrijević and Sahal–Bréchot, 1997. Here, only tables of Stark broadening parameters will be shown. Atomic energy levels needed for calculations have been taken from Martin and Zalubas (1983). Our results for 4 Si XI and 61 Si XIII multiplets are shown in Tables 1 and 2, for perturber densities  $10^{18} - 10^{23} \text{ cm}^{-3}$  and  $10^{16} - 10^{23} \text{ cm}^{-3}$  re-

**Table 1.** This table shows electron-, proton-, and He III-impact broadening parameters for Si XI for perturber densities of  $10^{18}$ – $10^{23}$  cm $^{-3}$  and temperatures from 500,000 up to 4,000,000 K. Stark broadening parameters for densities lower than tabulated, are linear with perturber density. Transitions and averaged wavelengths for the multiplet (in Å) are also given in the table. By dividing c by the corresponding full width at half maximum (Dimitrijević et al., 1991), we obtain an estimate for the maximum perturber density for which the line may be treated as isolated and tabulated data may be used. The asterisk identifies cases for which the collision volume multiplied by the perturber density (the condition for validity of the impact approximation) lies between 0.1 and 0.5.

**Table 2.** This table shows electron-, proton-, and He III-impact broadening parameters for Si XIII for perturber densities of  $10^{16} - 10^{23}$  cm $^{-3}$  and temperatures from 500,000 up to 6,000,000 K. The complete set of data is for the electron density of  $10^{19}$  cm $^{-3}$  and for lower densities only data needed for more accurate interpolation are given. Stark broadening parameters for densities lower than tabulated, are linear with perturber density. Transitions and averaged wavelengths for the multiplet (in Å) are also given in the table. By dividing c by the corresponding full width at half maximum (Dimitrijević et al., 1991), we obtain an estimate for the maximum perturber density for which the line may be treated as isolated and tabulated data may be used. The asterisk identifies cases for which the collision volume multiplied by the perturber density (the condition for validity of the impact approximation) lies between 0.1 and 0.5.

spectively. The temperature range is  $T = 500,000 - 4,000,000$  K for Si XI and  $500,000 - 6,000,000$  K for Si XIII. For Si XIII, the complete set of data is given for the perturber density of  $10^{19}\text{cm}^{-3}$ . For lower perturber densities, only data needed for better interpolation are given. Stark broadening parameters for densities lower than tabulated, or for transitions not tabulated for perturber densities lower than  $10^{19}\text{cm}^{-3}$  for Si XIII, are linear with perturber density. The parameter  $c$  (Dimitrijević and Sahal–Bréchot 1984), gives an estimate for the maximum perturber density for which the line may be treated as isolated when it is divided by the corresponding full width at half maximum. For each value given in Tables 1 and 2, the collision volume ( $V$ ) multiplied by the perturber density ( $N$ ) is much less than one and the impact approximation is valid (Sahal–Bréchot, 1969ab). Values for  $NV > 0.5$  are not given and values for  $0.1 < NV \leq 0.5$  are denoted by an asterisk. When the impact approximation is not valid, the ion broadening contribution may be estimated by using quasistatic approach (Sahal–Bréchot 1991 or Griem 1974). In the region between where neither of these two approximations is valid, a unified type theory should be used. For example in Barnard et al. (1974), a simple analytical formulas for such a case are given. The accuracy of the results obtained decreases when broadening by ion interactions becomes important.

The analysis and discussion of the results obtained, will be published in Dimitrijević and Sahal–Bréchot, 1997.
