## Abstract

Non-point invertible transformations are completely described for difference equations on the quad-graph and for their differential-difference analogues. As an illustration, these transformations are used to construct new examples of integrable equations and autotransformations of the Hietarinta equation.

## 1 Introduction

The present paper is devoted to invertible transformations for both discrete equations of the form

$$u_{i+1,j+1} = F(u_{i,j}, u_{i+1,j}, u_{i,j+1}),$$

and “semi-discrete” chains of the differential equations

$$(u_{i+1})_x = F(x, u_i, u_{i+1}, (u_i)_x).$$

Here  $j$  and  $j$  are integers,  $x$  is a continuous variable,  $u$  is a function of  $i, j$  and  $i, x$  for the first and the second equation, respectively. From now on, we shall omit  $i$  and  $j$  for brevity and, in particular, write the above equations in the form

$$u_{1,1} = F(u, u_{1,0}, u_{0,1}) \tag{1.1}$$

and

$$(u_1)_x = F(x, u, u_1, u_x). \tag{1.2}$$

We assume that  $F_u F_{u_{1,0}} F_{u_{0,1}} \neq 0$  for Eq. (1.1) and  $F_{u_x} \neq 0$  for Eq. (1.2). These conditions allows us to rewrite Eq. (1.1) in any of the following forms

$$u_{-1,-1} = \bar{F}(u, u_{-1,0}, u_{0,-1}), \tag{1.3}$$

$$u_{1,-1} = \hat{F}(u, u_{1,0}, u_{0,-1}), \tag{1.4}$$

$$u_{-1,1} = \tilde{F}(u, u_{-1,0}, u_{0,1}), \tag{1.5}$$

and Eq. (1.2) – in the form

$$(u_{-1})_x = \tilde{F}(x, u, u_{-1}, u_x). \tag{1.6}$$

Therefore, all “mixed shifts”  $u_{m,n} := u_{i+m,j+n}$  (for both positive and negative non-zero  $n$  and  $m$ ) can be expressed in terms of *dynamical variables*  $u_{k,0}, u_{0,l}$  by virtue of Eqs. (1.1), (1.3)–(1.5). Analogously,  $u_m^{(n)} := \partial^n u_{i+m} / \partial x^n$  for any non-zero  $m \in \mathbb{Z}$  and  $n \in \mathbb{N}$  can be expressed in terms of  $x$  and dynamical variables  $u_l := u_{i+l}, u^{(k)} := \partial^k u_i / \partial x^k u_i$  by virtue of Eqs. (1.2), (1.6). The

notation  $g[u]$  means that the function  $g$  depends on a finite number of the dynamical variables (and  $x$  if we consider Eq. (1.2)). The considerations in this paper are local (for example, we use the local implicit function theorem to obtain (1.3)–(1.6)) and, for simplicity, all functions are assumed to be locally analytical.

In addition to the point transformations  $v = g(u)$ , some of the equations (1.1) and (1.2) admit non-point transformations  $v = g[u]$  which are invertible in the sense of [15]. For example, the differential substitutions

$$v = \frac{u_x - \sin u}{2} \quad (1.7)$$

maps solutions of the differential-difference sine-Gordon equation [7, 13]

$$(u_1)_x - \sin u_1 = u_x + \sin u \quad (1.8)$$

into solutions of the equation

$$\frac{(v_1 - v)_x}{\sqrt{1 - (v_1 - v)^2}} = \pm(v_1 + v), \quad (1.9)$$

which is a semi-discrete version of the complex sine-Gordon equation. Here the sign of right-hand side of Eq. (1.9) coincides with the sign of the  $\cos u$  value<sup>1</sup>. Indeed,  $v_1 = (u_x + \sin u)/2$  follows from Eq. (1.8) and, together with (1.7), gives us

$$u_x = v_1 + v, \quad \sin u = v_1 - v \quad \implies \quad (v_1 - v)_x = u_x \cos u = \pm(v_1 + v)\sqrt{1 - (v_1 - v)^2}.$$

The inverse transformation can be found in [11]: the formula  $u = \frac{\pi}{2} \pm (\arcsin(v_1 - v) - \frac{\pi}{2})$  maps any real solution of Eq. (1.9) into a solution of Eq. (1.8).

This example belongs to the following class of non-point invertible transformations introduced in [16]. Let functions  $\varphi(x, y, z)$ ,  $\psi(x, y, z)$  satisfy the condition  $\varphi_y \psi_z - \varphi_z \psi_y \neq 0$  and Eq. (1.2) can be written in the form

$$\varphi(x, u_1, (u_1)_x) = \psi(x, u, u_x). \quad (1.10)$$

Then we rewrite (1.10) in the form of the system

$$v = \varphi(x, u, u_x), \quad v_1 = \psi(x, u, u_x), \quad (1.11)$$

express  $u, u_x$  in terms of  $v, v_1$  from (1.11) and obtain

$$u = p(x, v, v_1), \quad u_x = q(x, v, v_1). \quad (1.12)$$

The system (1.12) is equivalent to the equation

$$D_x(p(x, v, v_1)) = q(x, v, v_1), \quad (1.13)$$

where  $D_x$  denotes the total derivative with respect to  $x$ . The substitution  $v = \varphi(x, u, u_x)$  maps solutions of (1.10) into solutions of (1.13) and the transformation  $u = p(x, v, v_1)$  maps solutions of (1.13) back into solutions of (1.10).

It is easy to see that the same scheme can be applied to the pure discrete equations of the form

$$\varphi(u_{0,1}, u_{1,1}) = \psi(u, u_{1,0}), \quad (1.14)$$

where  $\varphi(y, z)$  and  $\psi(y, z)$  are functionally independent. Indeed, expressing  $u$  and  $u_{1,0}$  from

$$v = \varphi(u, u_{1,0}), \quad v_{0,1} = \psi(u, u_{1,0}), \quad (1.15)$$

---

<sup>1</sup>A local transformation of an equation may, generally speaking, generate different equations for different domains of the “jet space”. It is true for both point and non-point local transformations.

we obtain

$$u = p(v, v_{0,1}), \quad u_{1,0} = q(v, v_{0,1}) \quad (1.16)$$

and rewrite (1.16) in the form of the equivalent equation

$$p(v_{1,0}, v_{1,1}) = q(v, v_{0,1}). \quad (1.17)$$

Thus, the transformation  $v = \varphi(u, u_{1,0})$  maps solutions of (1.14) into solutions of (1.17) and the inverse transformation  $u = p(v, v_{0,1})$  maps solutions of (1.17) back into solutions of (1.14). The transformations (1.14)–(1.17) were, in fact, used in [17] without explicit formulation of the above scheme.

The main result of this paper is the proof of the following statement: any invertible transformation of Eqs. (1.1), (1.2) is a composition of shifts, point transformations and transformations (1.10)–(1.13), (1.14)–(1.17). Roughly speaking, Eqs. (1.1) and (1.2) have no non-point invertible transformations other than (1.14)–(1.17) and (1.10)–(1.13), respectively. The proof is similar to that was used in [15] for continuous equations (hyperbolic PDEs).

The invertible transformations allow us to obtain objects associated with integrability of Eqs. (1.13), (1.17) (such as conservation laws and higher symmetries) from the corresponding objects of Eqs. (1.10), (1.14) because we can express shifts and derivatives of  $u$  in terms of shifts and derivatives of  $v$ . Therefore, the invertible transformations may be useful for constructing new examples of integrable equations of the form (1.1), (1.2). To illustrate it, in section 4 we construct Darboux integrable equations related via invertible transformations to difference and differential-difference analogues of the Liouville equation. In addition, an example of constructing an equation possessing the higher symmetries is contained at the end of section 2. In this section we also demonstrate that the scheme (1.14)–(1.17) generates autotransformations of the Hietarinta equation.

## 2 Invertible transformations of discrete equations

We let  $T_i$  and  $T_j$  denote the operators of the forward shifts in  $i$  and  $j$  by virtue of Eq. (1.1). These operators are defined by the following rules:  $T_i(f(a, b, c, \dots)) = f(T_i(a), T_i(b), T_i(c), \dots)$  and  $T_j(f(a, b, c, \dots)) = f(T_j(a), T_j(b), T_j(c), \dots)$  for any function  $f$ ;  $T_i(u_{m,0}) = u_{m+1,0}$  and  $T_j(u_{0,n}) = u_{0,n+1}$ ;  $T_i(u_{0,n}) = T_j^{n-1}(F)$  for positive  $n$  and  $T_i(u_{0,n}) = T_j^{n+1}(\hat{F})$  for negative  $n$ ,  $T_j(u_{m,0}) = T_i^{m-1}(F)$  for positive  $m$  and  $T_j(u_{m,0}) = T_i^{m+1}(\tilde{F})$  for negative  $m$  (i.e. mixed variables  $u_{1,n}$  and  $u_{m,1}$  are expressed in terms of the dynamical variables by virtue of Eqs. (1.1), (1.4), (1.5)). The inverse (backward) shift operators  $T_i^{-1}$  and  $T_j^{-1}$  are defined in the similar way.

**Definition 1.** We say that a transformation  $v = f[u]$  maps the equation (1.1) into an equation  $v_{1,1} = G(v, v_{1,0}, v_{0,1})$  if

$$T_i T_j(f) = G(f, T_i(f), T_j(f)). \quad (2.1)$$

**Definition 2.** A transformation  $v = f[u]$  of Eq. (1.1) is called invertible if any of the dynamical variables  $u, u_{k,0}, u_{0,l}, k, l \in \mathbb{Z}$ , can be expressed as a function of a finite subset of the variables

$$v := f, v_{r,0} := T_i^r(f), v_{0,s} := T_j^s(f), r, s \in \mathbb{Z}. \quad (2.2)$$

We exclude all mixed variables  $v_{r,s}, rs \neq 0$ , from (2.2) because we consider only the cases when the transformation maps (1.1) into an equation of the form

$$v_{1,1} = G(v, v_{1,0}, v_{0,1}), \quad G_v G_{v_{1,0}} G_{v_{0,1}} \neq 0 \quad (2.3)$$

and the mixed variables can be expressed in terms of (2.2) by virtue of this equation.

It is easy to see that any shift  $w = v_{r,s}$  maps Eq. (2.3) into Eq. (2.3) again and the composition of the shift and an invertible transformation  $v = f[u]$  is invertible too. This leads to the following

**Definition 3.** Transformations  $v = f[u]$  and  $w = g[u]$  are called equivalent if there exist  $r, s \in \mathbb{Z}$  such that  $g = T_i^s T_j^r(f)$ .

**Proposition 1.** Let  $v = g[u]$  be an invertible transformation that maps Eq. (1.1) into Eq. (2.3). Then this transformation is equivalent to either a transformation of the form

$$w = f(u, u_{1,0}, u_{2,0}, \dots, u_{m,0}), \quad (2.4)$$

or a transformation of the form

$$w = f(u, u_{0,1}, u_{0,2}, \dots, u_{0,n}). \quad (2.5)$$

*Proof.* The transformation is equivalent to that of the form

$$v = h(u, u_{1,0}, \dots, u_{k,0}, u_{0,1}, \dots, u_{0,l}) \quad (2.6)$$

because we can eliminate “negative” variables  $u_{r,0}$ ,  $u_{0,s}$ ,  $r, s < 0$  from the transformation by shifts of  $g$ . We can express  $u$  as

$$\begin{aligned} u &= P(v_{a,0}, v_{a+1,0}, \dots, v_{b,0}, v_{0,c}, v_{0,c+1}, \dots, v_{0,d}) := \\ &:= P(T_i^a(h), T_i^{a+1}(h), \dots, T_i^b(h), T_j^c(h), T_j^{c+1}(h), \dots, T_j^d(h)) \end{aligned} \quad (2.7)$$

if the transformation is invertible. Differentiating Eq. (2.7) with respect to  $u_{k+b,0}$ , we obtain  $P_{v_{b,0}} T_i^b(h_{u_{k,0}}) = 0 \Rightarrow P_{v_{b,0}} = 0$  if  $b, k > 0$ . The analogous reasoning gives  $P_{v_{0,d}} = 0$  if  $d, l > 0$ . Thus,  $b, d \leq 0$  if  $kl \neq 0$ .

Let  $(T_i^{-1}(h))_{u_{-1,0}} (T_j^{-1}(h))_{u_{0,-1}} \neq 0$ . Then  $(T_i^a(h))_{u_{a,0}} (T_j^c(h))_{u_{0,c}} \neq 0$  for any negative  $a$  and  $c$ , and we obtain  $P_{v_{a,0}} = P_{v_{0,c}} = 0$  by differentiating Eq. (2.7) with respect to  $u_{a,0}$  and  $u_{0,c}$ . Therefore, either  $a = c = b = d = 0$  (i.e.  $u = P(h)$  that is possible only if  $k = l = 0$ ) or  $(T_i^{-1}(h))_{u_{-1,0}} (T_j^{-1}(h))_{u_{0,-1}} = 0$ . The latter equality means that either  $T_i^{-1}(h) = \tilde{h}(u, u_{1,0}, \dots, u_{k-1,0}, u_{0,1}, \dots, u_{0,l})$  or  $T_j^{-1}(h) = \tilde{h}(u, u_{1,0}, \dots, u_{k,0}, u_{0,1}, \dots, u_{0,l-1})$ , i.e. any invertible transformation of the form (2.6) with  $kl \neq 0$  is equivalent to a transformation  $\tilde{v} = \tilde{h}(u, u_{1,0}, \dots, u_{\tilde{k},0}, u_{0,1}, \dots, u_{0,\tilde{l}})$  such that  $\tilde{k}\tilde{l} < kl$ . Applying this conclusion several times, we obtain that (2.6) is equivalent to a transformation  $w = f(u, u_{1,0}, \dots, u_{m,0}, u_{0,1}, \dots, u_{0,n})$  with  $mn = 0$ .  $\square$

**Definition 4.** A transformation is called non-point if this transformation is not equivalent to any point transformation of the form  $w = g(u)$ .

Because the transformations  $v = f(u_{m,0})$  and  $v = f(u_{0,n})$  are equivalent to the point transformation  $w = f(u)$ , a transformation of the form (2.4) or (2.5) is non-point only if  $f$  depends on more than one variable. We use only this property of the non-point transformations in the proof of the following

**Theorem 1.** Let a non-point invertible transformation of the form (2.4) map Eq. (1.1) into Eq. (2.3). Then Eq. (1.1) can be written in the form  $\varphi(u_{0,1}, u_{1,1}) = \psi(u, u_{1,0})$ , where  $\varphi(y, z)$  and  $\psi(y, z)$  are functionally independent, and the transformation is equivalent to the composition of the invertible transformation  $w = \varphi(u, u_{1,0})$  and an invertible transformation of the form  $v = h(w, w_{1,0}, w_{2,0}, \dots, w_{m-1,0})$ . In particular, any non-point invertible transformation of the form  $v = f(u, u_{1,0})$  is equivalent to the composition of the transformation  $w = \varphi(u, u_{1,0})$  and a point transformation  $v = h(w)$ .

*Proof.* If  $f_{u_r,0} = 0$ ,  $r = \overline{0, s-1}$ ,  $f_{u_s,0} \neq 0$ , then the equivalent transformation  $v = T_i^{-s}(f[u])$  depends on  $u$ . Therefore, we can, without loss of generality, assume that  $f_u \neq 0$ . We also can write

$$\begin{aligned} u_{l,0} &= P_l(v_{a,0}, v_{a+1,0}, \dots, v_{b,0}, v_{0,c}, v_{0,c+1}, \dots, v_{0,d}) = \\ &= P_l(T_i^a(f), T_i^{a+1}(f), \dots, T_i^b(f), T_j^c(f), T_j^{c+1}(f), \dots, T_j^d(f)), \quad l = \overline{0, m} \end{aligned}$$

because the transformation is invertible. Differentiating these equalities with respect to  $u_{a,0}$ , we obtain  $(P_l)_{v_{a,0}} T_i^a(f_u) = 0 \Rightarrow (P_l)_{v_{a,0}} = 0$  if  $a < 0$ . The similar reasoning gives  $(P_l)_{v_{b,0}} = 0$  if  $b > 0$ . Thus,

$$u_{l,0} = P_l(T_j^c(f), T_j^{c+1}(f), \dots, T_j^d(f)), \quad l = \overline{0, m}.$$

Let  $c < 0$  and  $s$  be the biggest negative integer such that  $(T_j^s(f))_{u_{0,-1}} \neq 0$ . If  $s \geq c$ , then  $T_j^c(f)$  depends on  $u_{0,c-s-1}$  and  $(P_l)_{u_{0,c-s-1}} = (P_l)_{v_{0,c}} (T_j^c(f))_{u_{0,c-s-1}} = 0 \Rightarrow (P_l)_{v_{0,c}} = 0$ . Hence  $s < c$ , i.e.  $(T_j^r(f))_{u_{0,-1}} = 0$  for all  $r \geq c$ . This implies  $T_j^c(f) = g(u, u_{1,0}, \dots, u_{m,0})$  and

$$u_{l,0} = P_l(g, T_j(g), \dots, T_j^{\tilde{d}}(g)), \quad l = \overline{0, m}. \quad (2.8)$$

If  $c \geq 0$ , then Eqs. (2.8) holds too, with  $g = f$  and  $\tilde{d} = d$ .

Repeating the above argumentation, we prove that  $(T_j^r(g))_{u_{0,1}} = 0$  for all  $r \leq \tilde{d}$ . Let us consider the operators  $X = T_j^{-1} \partial_{u_{0,1}} T_j$  (cp. [4]) and  $Y = [\partial_{u_{0,-1}}, X]$ , where  $\partial_z := \frac{\partial}{\partial z}$ . These operators have the form

$$X = \partial_u + \sum_{l=1}^m \xi_l \partial_{u_{l,0}}, \quad Y = \sum_{l=1}^m \nu_l \partial_{u_{l,0}}$$

for functions of  $u, u_{1,0}, \dots, u_{m,0}$ . According to Eq. (2.8), the set  $\{g, T_j(g), \dots, T_j^{\tilde{d}}(g)\}$  must contain  $m+1$  functionally independent functions because  $u_{l,0}$ ,  $l = \overline{0, m}$ , are functionally independent. Hence the system  $X(z) = 0$ ,  $Y(z) = 0$  has  $m$  functionally independent solutions depending on  $u, u_{1,0}, \dots, u_{m,0}$  and the vectors  $(1, \xi_1, \dots, \xi_m)$ ,  $(0, \nu_1, \dots, \nu_m)$  must be collinear. The latter is possible only if  $\nu_l = 0$  for all  $l = \overline{0, m}$ . In particular,

$$\begin{aligned} \nu_1 &= [T_j^{-1}(F_{u_{0,1}})]_{u_{0,-1}} = 0 \Rightarrow T_j^{-1}(F_{u_{0,1}}) = \alpha(u, u_{1,0}) \Rightarrow F_{u_{0,1}} = T_j(\alpha) = \alpha(u_{0,1}, F) \Rightarrow \\ &\Rightarrow F_{uu_{0,1}} = \alpha_{u_{1,0}}(u_{0,1}, F) F_u, F_{u_{1,0}u_{0,1}} = \alpha_{u_{1,0}}(u_{0,1}, F) F_{u_{1,0}} \Rightarrow (\ln(F_{u_{1,0}}) - \ln(F_u))_{u_{0,1}} = 0 \Rightarrow \\ &\Rightarrow F_{u_{1,0}} - \beta(u, u_{1,0}) F_u = 0 \Rightarrow F = E(\psi(u, u_{1,0}), u_{0,1}), \end{aligned}$$

where  $\psi$  is a solution of the equation  $\psi_{u_{1,0}} - \beta(u, u_{1,0}) \psi_u = 0$ . Thus, Eq. (1.1) can be written in the form (1.14).

We can express  $g$  in terms of  $u, \varphi(u, u_{1,0}), \varphi(u_{1,0}, u_{2,0}), \dots, \varphi(u_{m-1,0}, u_{m,0})$ :

$$g = h(u, \varphi(u, u_{1,0}), \varphi(u_{1,0}, u_{2,0}), \dots, \varphi(u_{m-1,0}, u_{m,0})),$$

It is proved above that  $X(g) = 0$ . Taking this fact into account, we obtain  $h_u = 0$  because  $X(g) = X(h) = T_j^{-1}[h_u(u_{0,1}, \psi(u, u_{1,0}), \dots, \psi(u_{m-1,0}, u_{m,0}))] = h_u$ . This means that the transformation (2.4) is equivalent to the composition of the transformation  $w = \varphi(u, u_{1,0})$  and the transformation  $v = h(w, w_{1,0}, w_{2,0}, \dots, w_{m-1,0})$ . The latter transformation is invertible because

$$w = \varphi(P_0, P_1) = \tilde{P}_0(g, T_j(g), \dots, T_j^{\tilde{d}}(g)) = \tilde{P}_0(h, T_j(h), \dots, T_j^{\tilde{d}}(h))$$

by virtue of Eq. (2.8). The expressions for other dynamical variables can be obtained by the formulas  $w_{0,r} = T_j^r(\tilde{P}_0)$  and  $w_{s,0} = T_i^s(\tilde{P}_0)$ .

Let  $\varphi$  and  $\psi$  be functionally dependent. Then Eq. (1.14) has the form  $\varphi(u_{0,1}, u_{1,1}) = E(\varphi(u, u_{1,0}))$  and all functions  $T_j^r(g)$  can be expressed in terms of  $\varphi(u, u_{1,0})$ ,  $\varphi(u_{1,0}, u_{2,0})$ ,  $\dots$ ,  $\varphi(u_{m-1,0}, u_{m,0})$  ( $T_j(g) = h(E(\varphi(u, u_{1,0})), \dots, E(\varphi(u_{m-1,0}, u_{m,0})))$  and so on). Hence the set  $\{g, T_j(g), \dots, T_j^{\bar{d}}(g)\}$  contains no more than  $m$  functionally independent functions. But we prove above that this set must contain  $m+1$  functionally independent functions if the transformation is invertible. Therefore,  $\varphi$  and  $\psi$  must be functionally independent if Eq. (1.14) admits an invertible transformation of the form  $v = f(u, u_{1,0}, u_{2,0}, \dots, u_{m,0})$ .  $\square$

It is not always easy to see whether Eq. (1.1) can be represented in the form (1.14). For example, at first glance it seems that the equation

$$v_{1,1} = \frac{v(v_{1,0} + 1)}{v(v_{0,1} - v_{1,0}) + v_{0,1} + 1} \quad (2.9)$$

does not admit an invertible transformation of the form  $u = \varphi(v, v_{1,0})$ . But in reality we can rewrite this equation as

$$\frac{v_{1,1} + 1}{v_{0,1}v_{1,1} - 1} = \frac{v + 1}{v_{1,0}v - 1}$$

and relate it to the equation

$$(u_{1,1} - 1)(u_{0,1} + 1) = (u_{1,0} + 1)(u - 1) \quad (2.10)$$

via the invertible transformation

$$u = -2\frac{v_{1,0} + 1}{vv_{1,0} - 1} - 1, \quad v = \frac{u_{0,1} - 1}{u + 1}.$$

Therefore, it is useful to reformulate our result in the following form.

**Corollary 1.** *The equation (1.1) admits a non-point invertible transformation of the form (2.4) into an equation of the form (2.3) if and only if both the conditions*

$$\left(\frac{F_{u_{1,0}}}{F_u}\right)_{u_{0,1}} = 0, \quad F_u + F_{u_{1,0}}T_j^{-1}(F_{u_{0,1}}) \neq 0$$

are satisfied.

*Proof.* If Eq. (1.1) is represented in the form (1.14), then the right-hand side  $F$  of (1.1) is determined as an implicit function from the identity

$$\varphi(u_{0,1}, F) = \psi(u, u_{1,0}). \quad (2.11)$$

Differentiating this identity with respect to  $u$  and  $u_{1,0}$ , we obtain

$$T_j(\varphi_{u_{1,0}}(u, u_{1,0}))F_u = \psi_u(u, u_{1,0}), \quad T_j(\varphi_{u_{1,0}}(u, u_{1,0}))F_{u_{1,0}} = \psi_{u_{1,0}}(u, u_{1,0}). \quad (2.12)$$

Therefore,  $F_{u_{1,0}}/F_u$  does not depend on  $u_{0,1}$ . Conversely, if  $F_{u_{1,0}}/F_u = \beta(u, u_{1,0})$ , then  $F = E(\psi(u, u_{1,0}), u_{0,1})$  and (1.1) can be rewritten in the form (1.14).

Differentiating (2.11) with respect to  $u_{0,1}$ , we obtain  $F_{u_{0,1}} = -T_j(\varphi_u/\varphi_{u_{1,0}})$ . This expression and Eq. (2.12) allow us to rewrite the functional independence condition for  $\varphi$ ,  $\psi$  in the following way

$$\begin{aligned} \varphi_{u_{1,0}}(u, u_{1,0})\psi_u(u, u_{1,0}) - \varphi_u(u, u_{1,0})\psi_{u_{1,0}}(u, u_{1,0}) &= \varphi_{u_{1,0}}(\psi_u + T_j^{-1}(F_{u_{0,1}})\psi_{u_{1,0}}) = \\ &= T_j(\varphi_{u_{1,0}})\varphi_{u_{1,0}}(F_u + T_j^{-1}(F_{u_{0,1}})F_{u_{1,0}}) \neq 0. \end{aligned}$$

$\square$

Naturally, the propositions analogous to Theorem 1 and Corollary 1 are valid for invertible transformations of the form  $v = f(u, u_{0,1}, u_{0,2}, \dots, u_{0,n})$  too.

Returning to Eqs. (2.9)–(2.10), we note that Eq. (2.10) was introduced in [12] in a slightly different form. This equation has also been used in [10] as an example of an equation which is inconsistent around the cube (in the sense of [1]) but possesses the higher symmetries. Therefore, we can obtain symmetries of Eq. (2.9) from symmetries of Eq. (2.10).

Indeed, if a transformation  $v = f(u, u_{0,1})$  maps Eq. (1.1) into Eq. (2.3), then differentiation of (2.1) with respect to  $\tau$  by virtue a symmetry  $u_\tau = \xi[u]$  of Eq. (1.1) gives us

$$L_G ((f_{u_{0,1}} T_j + f_u)(\xi[u])) = (\lambda[u] T_j + \mu[u]) (L_F(\xi[u])) ,$$

where

$$L_G = T_i T_j + G_{v_{1,0}} T_i + G_{v_{0,1}} T_j + G_v , \quad L_F = T_i T_j + F_{u_{1,0}} T_i + F_{u_{0,1}} T_j + F_u .$$

Because  $L_F(\xi[u]) = 0$  by definition of symmetry, we see that  $v_\tau = f_{u_{0,1}} T_j(\xi[u]) + f_u \xi[u]$  (after rewriting in terms of  $v$  and its shifts) is a symmetry of Eq. (2.3). Applying this, for example, to the three-point symmetries

$$u_\tau = (u^2 - 1)(u_{1,0} - u_{-1,0}), \quad u_\tau = (u^2 - 1) \left( \frac{1}{u_{0,1} + u} - \frac{1}{u + u_{0,-1}} \right)$$

of Eq. (2.10), we obtain the symmetries

$$v_\tau = (v + 1)^2 \left( \frac{1}{vv_{1,0} - 1} - \frac{1}{vv_{-1,0} - 1} \right), \quad v_\tau = v \left( \frac{1}{v_{0,1} + 1} - \frac{1}{v_{0,-1} + 1} \right)$$

of Eq. (2.9).

The Hietarinta [6] equation<sup>2</sup>

$$u_{1,1}(u + \beta)(u_{0,1} + \alpha) = u_{0,1}(u + \alpha)(u_{1,0} + \beta) \tag{2.13}$$

is another interesting example. The invertible transformations

$$v = \frac{u_{1,0}(u + \alpha)}{u} - \alpha, \quad w = \frac{\beta u_{0,1}}{\beta + u - u_{0,1}}$$

map this equation into Eq. (2.13) again. In addition, the Hietarinta equation is linearizable [14]. We note that the above properties of Eq. (2.13) are similar to those of the continuous equation

$$u_{xy} = (\alpha(x, y)e^u)_x + (\beta(x, y)e^{-u})_y + \gamma(x, y)$$

which was considered in [15].

### 3 Invertible transformations of differential-difference equations

We let  $T$  denote the operator of the forward shift in  $i$  by virtue of Eq. (1.2). This operator is defined by the following rules:  $T(f(a, b, c, \dots)) = f(T(a), T(b), T(c), \dots)$  for any function  $f$ ;  $T(u_m) = u_{m+1}$ ;  $T(u^{(n)}) = D_x^{n-1}(F)$  (mixed variables  $u_1^{(n)}$  are expressed in terms of the dynamical variables by virtue of Eq. (1.2)). Here

$$D_x = \frac{\partial}{\partial x} + u^{(1)} \frac{\partial}{\partial u} + \sum_{k=1}^{\infty} \left( u^{(k+1)} \frac{\partial}{\partial u^{(k)}} + T^{(k-1)}(F) \frac{\partial}{\partial u_k} + T^{(1-k)}(\tilde{F}) \frac{\partial}{\partial u_{-k}} \right),$$

i.e.  $D_x$  is total derivative with respect to  $x$  by virtue of Eqs. (1.2), (1.6). The inverse (backward) shift operator  $T^{-1}$  is defined in the similar way.

<sup>2</sup>We write this equation in the form used in [14]

**Definition 5.** We say that a transformation  $v = f[u]$  maps Eq. (1.2) into an equation

$$(v_1)_x = G(x, v, v_1, v_x), \quad G_{v_x} \neq 0 \quad (3.1)$$

if  $D_x T(f) = G(x, f, T(f), D_x(f))$ .

**Definition 6.** A transformation  $v = f[u]$  of Eq. (1.2) is called invertible if any of the dynamical variables  $u, u_k, k \in \mathbb{Z}, u^{(l)}, l \in \mathbb{N}$  can be expressed as a function of a finite subset of the variables

$$x, v := f, v_r := T^r(f), v^{(s)} := D_x^s(f), r \in \mathbb{Z}, s \in \mathbb{N}.$$

**Definition 7.** Transformations  $v = f[u]$  and  $w = g[u]$  are called equivalent if there exists  $r \in \mathbb{Z}$  such that  $g = T^r(f)$ .

**Proposition 2.** Let a transformation of the form  $v = g[u]$  be invertible and map Eq. (1.2) into Eq. (3.1). Then this transformation is equivalent to either a transformation of the form

$$w = f(x, u, u_1, u_2, \dots, u_m), \quad (3.2)$$

or a transformations of the form

$$w = f(x, u, u^{(1)}, u^{(2)}, \dots, u^{(n)}). \quad (3.3)$$

**Definition 8.** A transformation is called non-point if this transformation is not equivalent to any point transformation of the form  $w = g(x, u)$ .

It is easy to see that a transformation of the form (3.2) or (3.3) is non-point only if  $f$  depends on more than one of the variables  $u, u_1, \dots, u_m$  or on at least one of the variables  $u^{(1)}, \dots, u^{(n)}$ , respectively.

**Theorem 2.** Let a non-point invertible transformation of the form (3.3) map Eq. (1.2) into Eq. (3.1). Then Eq. (1.2) can be written in the form  $\varphi(x, u_1, (u_1)_x) = \psi(x, u, u_x)$ , where  $\varphi(x, y, z)$  and  $\psi(x, y, z)$  satisfy the condition  $\varphi_y \psi_z - \varphi_z \psi_y \neq 0$ , and the transformation is equivalent to the composition of the invertible transformation  $w = \varphi(x, u, u_x)$  and an invertible transformation of the form  $v = h(x, w, w^{(1)}, w^{(2)}, \dots, w^{(n-1)})$ . In particular, any non-point invertible transformation of the form  $v = f(x, u, u_x)$  is equivalent to the composition of the transformation  $w = \varphi(x, u, u_x)$  and a point transformation  $v = h(x, w)$ .

**Corollary 2.** The equation (1.2) admits a non-point invertible transformation of the form (3.3) into an equation of the form (3.1) if and only if both the conditions

$$F_u F_{u_x u_1} - F_{u u_1} F_{u_x} = 0, \quad F_u + F_{u_x} T^{-1}(F_{u_1}) \neq 0$$

are satisfied.

**Theorem 3.** Let a non-point invertible transformation of the form (3.2) map Eq. (1.2) into Eq. (3.1). Then Eq. (1.2) can be written in the form  $D_x(p(x, u, u_1)) = q(x, u, u_1)$ , where  $p(x, y, z)$  and  $q(x, y, z)$  satisfy the condition  $p_y q_z - p_z q_y \neq 0$ , and the transformation is the composition of the transformation  $w = p(x, u, u_1)$  and an invertible transformation of the form  $v = h(x, w, w_1, \dots, w_{m-1})$ . In particular, any non-point invertible transformation of the form  $v = f(x, u, u_1)$  is the composition of the transformation  $w = p(x, u, u_1)$  and a point transformation  $v = h(x, w)$ .

**Corollary 3.** The equation (1.2) admits a non-point invertible transformation of the form (3.2) into an equation of the form (3.1) if and only if Eq. (1.2) has the form

$$(u_1)_x = a(x, u, u_1)u_x + b(x, u, u_1),$$

where  $a$  and  $b$  satisfy the condition  $a_x + a_{u_1} b - a b_{u_1} - b_u \neq 0$ .

For brevity, we omit the proofs of the above propositions because they are very similar to the proofs for discrete equations.

## 4 Examples: the transformations of Liouville equation analogues

A special class of integrable equations of the form

$$u_{xy} = F(x, y, u, u_x, u_y) \quad (4.1)$$

consists of equations for which there exist both a differential substitution of the form  $v = X(x, y, u_x, u_{xx}, \dots)$  and a substitution of the form  $w = Y(x, y, u_y, u_{yy}, \dots)$  that map (4.1) into the equations  $v_y = 0$  and  $w_x = 0$ , respectively. Such equations are called Darboux integrable or equations of the Liouville type. They not only are C-integrable (in accordance with the term of [3]) but also possess infinitely many symmetries of arbitrary high order [18, 19]. The complete classification of the Darboux integrable equations (4.1) has been performed in [19]. Equations with the analogous properties exist among equations of the form (1.1) and (1.2) too, but the classification of such equations is completed for a special case of Eq. (1.2) only [5]. Therefore, deriving new examples of discrete and semi-discrete Darboux integrable equations from already known equations may be useful (for example, to check the completeness of a future classification).

### 4.1 Discrete equations

The first example is the discrete Liouville equation

$$u_{1,1} = \frac{(u_{1,0} - 1)(u_{0,1} - 1)}{u} \quad (4.2)$$

from [9]. According to [2], this equation has the integrals

$$I[u] = \left( \frac{u_{2,0}}{u_{1,0} - 1} + 1 \right) \left( \frac{u - 1}{u_{1,0}} + 1 \right), \quad J[u] = \left( \frac{u_{0,2}}{u_{0,1} - 1} + 1 \right) \left( \frac{u - 1}{u_{0,1}} + 1 \right), \quad (4.3)$$

i.e. functions  $I[u]$ ,  $J[u]$  such that  $T_j(I[u]) = I[u]$ ,  $T_i(J[u]) = J[u]$ . In addition, Eq. (4.2) is linearizable: the substitution

$$u = \frac{z_{0,1}z_{1,0}}{(z_{1,0} - z)(z_{0,1} - z)} \quad (4.4)$$

maps solutions of the equation

$$z_{1,1} = z_{1,0} + z_{0,1} - z \quad (4.5)$$

into solutions of (4.2).

It is easy to see that (4.2) can be written in the form  $T_j(\varphi(u, u_{1,0})) = \psi(u, u_{1,0})$  and the scheme (1.14)–(1.17) is applicable to this equation:

$$\begin{aligned} v = \varphi &= \frac{u_{1,0}}{u - 1}, & v_{0,1} = \psi &= \frac{u_{1,0} - 1}{u}; \\ u = p &= \frac{v + 1}{v - v_{0,1}}, & u_{1,0} = q &= v \frac{v_{0,1} + 1}{v - v_{0,1}}; \\ \frac{v_{1,0} + 1}{v_{1,0} - v_{1,1}} &= \frac{v_{0,1} + 1}{v - v_{0,1}} v. \end{aligned}$$

Thus, we obtain the equation

$$v \frac{v_{1,1} - v_{1,0}}{v_{0,1} - v} = \frac{v_{1,0} + 1}{v_{0,1} + 1} \quad (4.6)$$

that is related to the discrete Liouville equation via the invertible transformation  $v = u_{1,0}/(u-1)$ . Substituting the expressions of  $u, u_{0,1}, u_{1,0}, \dots$  in terms of  $v, v_{0,1}, v_{1,0}, \dots$  into (4.3), we obtain the integrals of Eq. (4.6):

$$I[v] = v_{1,0} + \frac{v_{1,0} + 1}{v}, \quad J[v] = \frac{(v_{0,3} - v_{0,1})(v_{0,2} - v)}{(v_{0,3} - v_{0,2})(v_{0,1} - v)}.$$

The composition

$$v = \frac{z_{0,2}(z_{1,0} - z)}{z(z_{2,0} - z_{1,0})}$$

of the transformation  $v = u_{1,0}/(u-1)$  and (4.4) allows us to construct the solution

$$v = \frac{(\alpha_{i+2} + \beta_j)(\alpha_{i+1} - \alpha_i)}{(\alpha_i + \beta_j)(\alpha_{j+2} - \alpha_{i+1})}$$

of Eq. (4.6) from the general solution  $z = \alpha_i + \beta_j$  of (4.5), where  $\alpha_i$  and  $\beta_j$  are arbitrary.

Equation (4.6) can be written in the form  $T_j(\varphi) = \psi$  but  $\varphi$  and  $\psi$  are functionally dependent ( $\varphi = \psi = I[v]$ ). According to Theorem 1, this fact implies that (4.6) has no non-point invertible transformation of the form  $\tilde{v} = f(v, v_{1,0}, \dots, v_{n,0})$  and hence Eq. (4.2) admits, up to equivalence, only the first order invertible transformations ( $v = f(u_{1,0}/(u-1))$  and  $w = g(u_{0,1}/(u-1))$  only).

Applying Corollary 1, we see that the other discrete version [8] of the Liouville equation

$$v_{1,1} = \frac{v_{1,0}v_{0,1} - 1}{v}$$

does not admit a non-point invertible transformation. This equation is mapped into (4.2) via the non-invertible transformation  $u = v_{1,0}v_{0,1}$  and has the integrals

$$I[v] = \left( \frac{v_{3,0}}{v_{1,0}} + 1 \right) \left( \frac{v}{v_{2,0}} + 1 \right), \quad J[v] = \left( \frac{v_{0,3}}{v_{0,1}} + 1 \right) \left( \frac{v}{v_{0,2}} + 1 \right).$$

## 4.2 Differential-difference equations

Let us consider the following analogue of the Liouville equation:

$$(u_1)_x = u_1 \left( u_1 + \frac{u_x}{u} + u \right). \quad (4.7)$$

This equation has the integrals

$$X[u] = 2\frac{u_{xx}}{u} - 3\frac{u_x^2}{u^2} - u^2, \quad I[u] = \left( 1 + \frac{u_1}{u_2} \right) \left( 1 + \frac{u_1}{u} \right),$$

i.e. functions  $X[u], I[u]$  such that  $T(X) = X, D_x(I) = 0$ . Like the discrete and continuous Liouville equations, Eq. (4.7) is linearizable: the substitution

$$u = \frac{(z_1 - z)z_x}{z_1 z} \quad (4.8)$$

maps solutions of the equation

$$(z_1)_x = z_x \quad (4.9)$$

into solutions of (4.7). The above information and some other details about Eq. (4.7) can be found in [2].

Eq. (4.7) can be written as

$$\frac{(u_1)_x}{u_1} - u_1 = \frac{u_x}{u} + u.$$

Applying the scheme (1.10)–(1.13), we obtain

$$\begin{aligned} v &= \frac{1}{2} \left( \frac{u_x}{u} - u \right), & v_1 &= \frac{1}{2} \left( \frac{u_x}{u} + u \right); \\ u &= v_1 - v, & u_x &= v_1^2 - v^2; \\ (v_1 - v)_x &= v_1^2 - v^2. \end{aligned} \quad (4.10)$$

Thus, the invertible transformation  $v = (u_x/u - u)/2$  maps Eq. (4.7) into the sequence of the coupled Riccati equations (4.10). Expressing  $X[u]$  and  $I[u]$  in terms of  $v, v_1, v_x, \dots$ , we obtain the integrals

$$X[v] = v_x - v^2, \quad I[v] = \frac{(v_3 - v_1)(v_2 - v)}{(v_3 - v_2)(v_1 - v)}.$$

of Eq. (4.10). The composition

$$v = \frac{z_{xx}}{2z_x} - \frac{z_x}{z}$$

of the invertible transformation and (4.8) generates the solution

$$v = \frac{\beta_{xx}}{2\beta_x} - \frac{\beta_x}{\alpha_i + \beta} \quad (4.11)$$

of Eq. (4.10) from the general solution  $z = \alpha_i + \beta(x)$  of (4.9), where  $\alpha_i$  and  $\beta(x)$  are arbitrary. Eq. (4.10) was used in [2] as an example of an equation admitting the integrals and the solution (4.11) was constructed in this article by another method (directly from the equation  $X[v] = \xi(x)$ ).

Moreover, Eq. (4.7) can be represented in the form (1.13) too. Applying the scheme (1.10)–(1.13) in the reverse order, we get

$$\begin{aligned} w &= p = \frac{u_1}{u}, & w_x &= q = \frac{u_1^2}{u} + u_1; \\ u &= \frac{w_x}{(w+1)w}, & u_1 &= \frac{w_x}{w+1}; \\ \frac{(w_1)_x}{(w_1+1)w_1} &= \frac{w_x}{w+1} \end{aligned}$$

and see that the invertible transformation  $w = u_1/u$  maps (4.7) into the equation

$$(w_1)_x = w_x w_1 \frac{w_1 + 1}{w + 1}. \quad (4.12)$$

As above, we construct the integrals

$$X[w] = 2 \frac{w_{xxx}}{w_x} - 3 \frac{w_{xx}^2}{w_x^2}, \quad I[w] = \frac{(w_1 + 1)(w + 1)}{w_1}.$$

of Eq. (4.12) by expressing  $X[u]$  and  $I[u]$  in terms of  $w, w_1, w_x, \dots$ , and obtain its solution

$$w = \frac{(\alpha_{i+2} - \alpha_{i+1})(\alpha_i + \beta(x))}{(\alpha_{i+1} - \alpha_i)(\alpha_{i+2} + \beta(x))}$$

with arbitrary  $\alpha_i$  and  $\beta(x)$  by applying the composition

$$w = \frac{(z_2 - z_1)z}{(z_1 - z)z_2}$$

of the transformations  $w = u_1/u$  and (4.8) to the general solution  $z = \alpha_i + \beta(x)$  of Eq. (4.9).

The semi-discrete Liouville equation (4.7) is a special case of the Darboux integrable equation

$$(u_1)_x = u_x + \sqrt{Ce^{2u_1} + Be^{(u_1+u)} + Ce^{2u}}. \quad (4.13)$$

that was introduced in [5]. Indeed, replacing  $u$  in (4.7) by  $\exp(u)$ , we obtain Eq. (4.13) with  $C = 1$ ,  $B = 2$ . Without loss of generality, we can assume that the constant  $C$  in Eq. (4.13) equals 1 or 0 because  $C$  can be scaled via the point transformation  $u = \tilde{u} + \gamma$ . Applying Corollary 2, we see that Eq. (4.13) admits an invertible transformation of the form  $v = f(x, u, u_x)$  only if  $B = 2C$ . The invertible transformations

$$w = e^{u_1-u}, \quad e^u = \frac{w_x}{w\sqrt{Cw^2 + Bw + C}}$$

relate (4.13) to the equation

$$(w_1)_x = w_1 w_x \sqrt{\frac{Cw_1^2 + Bw_1 + C}{Cw^2 + Bw + C}}. \quad (4.14)$$

The later equation has the integrals

$$X[w] = 2\frac{w_{xxx}}{w_x} - 3\left(\frac{w_{xx}}{w_x}\right)^2 + \frac{3w_x^2(B^2 - 4C^2)}{4(Cw^2 + Bw + C)},$$

$$I[w] = \int^{w_1} \frac{ds}{s\sqrt{Cs^2 + Bs + C}} - \int^w \frac{ds}{\sqrt{Cs^2 + Bs + C}}$$

and can not be reduced to Eq. (4.12) via a point transformation because Eq. (4.14), in contrast to Eq. (4.12), does not admit an invertible transformation of the form  $v = f(x, w, w_x, w_{xx})$  if  $B \neq 2C$ .
