# Generalization of a theorem of Clunie and Hayman

Matthew Barrett and Alexandre Eremenko<sup>\*</sup>

November 18, 2010

#### Abstract

Clunie and Hayman proved that if the spherical derivative ||f'|| of an entire function satisfies  $||f'||(z) = O(|z|^{\sigma})$  then  $T(r, f) = O(r^{\sigma+1})$ . We generalize this to holomorphic curves in projective space of dimension *n* omitting *n* hyperplanes in general position. MSC 32Q99, 30D15.

### Introduction

We consider holomorphic curves  $f : \mathbf{C} \to \mathbf{P}^n$ ; for the general background on the subject we refer to [7]. The Fubini–Study derivative ||f'|| measures the length distortion from the Euclidean metric in  $\mathbf{C}$  to the Fubini–Study metric in  $\mathbf{P}^n$ . The explicit expression is

$$||f'||^2 = ||f||^{-4} \sum_{i < j} |f'_i f_j - f_i f'_j|^2,$$

where  $(f_0, \ldots, f_n)$  is a homogeneous representation of f (that is the  $f_j$  are entire functions which never simultaneously vanish), and

$$||f||^2 = \sum_{j=0}^n |f_j|^2.$$

See [3] for a general discussion of the Fubini-Study derivative.

<sup>\*</sup>Supported by NSF grant DMS-055279 and by the Humboldt Foundation.

We recall that the Nevanlinna–Cartan characteristic is defined by

$$T(r,f) = \int_0^r \frac{dt}{t} \left( \frac{1}{\pi} \int_{|z| \le t} \|f'\|^2(z) dm(z) \right),$$

where dm is the area element in **C**. So the condition

$$\limsup_{z \to \infty} |z|^{-\sigma} \|f'(z)\| \le K < \infty$$
(1)

implies

$$\limsup_{r \to \infty} \frac{T(r, f)}{r^{2\sigma + 2}} < \infty.$$
(2)

Clunie and Hayman [4] found that for curves  $\mathbf{C} \to \mathbf{P}^1$  omitting one point in  $\mathbf{P}^1$ , a stronger conclusion follows from (1), namely

$$\limsup_{r \to \infty} \frac{T(r, f)}{r^{\sigma+1}} \le KC(\sigma).$$
(3)

In the most important case  $\sigma = 0$ , a different proof of this fact for n = 1 is due to Pommerenke [8]. Pommerenke's method gives the exact constant C(0). In this paper we prove that this phenomenon persists in all dimensions.

**Theorem.** For holomorphic curves  $f : \mathbf{C} \to \mathbf{P}^n$  omitting *n* hyperplanes in general position, condition (1) implies (3) with an explicit constant  $C(n, \sigma)$ .

In [6], the case  $\sigma = 0$  was considered. There it was proved that holomorphic curves in  $\mathbf{P}^n$  with bounded spherical derivative and omitting n hyperplanes in general position must satisfy T(r, f) = O(r). With a stronger assumption that f omits n + 1 hyperplanes this was earlier established by Berteloot and Duval [2] and by Tsukamoto [9]. The proof in [6] has two drawbacks: it does not extend to arbitrary  $\sigma \ge 0$ , and it is non-constructive; unlike Clunie–Hayman and Pommerenke's proofs mentioned above, it does not give an explicit constant in (3).

It is shown in [6] that the condition that n hyperplanes are omitted is exact: there are curves in any dimension n satisfying (1),  $T(r, f) \sim cr^{2\sigma+2}$ and omitting n-1 hyperplanes.

#### Preliminaries

Without loss of generality we assume that the omitted hyperplanes are given in the homogeneous coordinates by the equations  $\{w_j = 0\}, 1 \le j \le n$ . We fix a homogeneous representation  $(f_0, \ldots, f_n)$  of our curve, where  $f_j$  are entire functions, and  $f_n = 1$ . Then

$$u = \log \sqrt{|f_0|^2 + \ldots + |f_n|^2}$$
(4)

is a positive subharmonic function, and Jensen's formula gives

$$T(r,f) = \frac{1}{2\pi} \int_{-\pi}^{\pi} u(re^{i\theta})d\theta - u(0) = \int_{0}^{r} \frac{n(t)}{t} dt,$$

where  $n(t) = \mu(\{z : |z| \le t\})$ , and  $\mu = \mu_u$  is the Riesz measure of u, that is the measure with the density

$$\frac{1}{2\pi}\Delta u = \frac{1}{\pi} \|f'\|^2.$$
 (5)

This measure  $\mu$  is also called Cartan's measure of f. Positivity of u and (2) imply that all  $f_j$  are of order at most  $2\sigma + 2$ , normal type. As  $f_j(z) \neq 0, 1 \leq j \leq n$  we conclude that

$$f_j = e^{P_j}, \quad 1 \le j \le n,$$

where

 $P_j$  are polynomials of degree at most  $2\sigma + 2$ . (6)

We need two lemmas from potential theory.

**Lemma 1.** [6] Let v be a non-negative harmonic function in the closure of the disc B(a, R), and assume that  $v(z_1) = 0$  for some point  $z_1 \in \partial B(a, R)$ . Then

$$v(a) \le 2R |\nabla v(z_1)|.$$

**Lemma 2.** Let v be a non-negative superharmonic function in the closure of the disc B(a, R), and suppose that  $v(z_1) = 0$  for some  $z_1 \in \partial B(a, R)$ . Then

$$|\mu_v(B(a, R/2))| \le 3R |\nabla v(z_1)|.$$

*Proof.* Function v(a + Rz) satisfies the conditions of the lemma with R = 1. So it is enough to prove the lemma with a = 0 and R = 1. Let

$$w(z) = \int_{|\zeta| < 1} G(z, \zeta) d\mu_v(\zeta)$$

be the Green potential of  $\mu_v$ . Then  $w \leq v$  and  $w(z_1) = v(z_1)$  which implies that

$$|\nabla v(z_1)| \ge \left|\frac{\partial w}{\partial |z|}(z_1)\right|.$$

Minimizing  $|\partial G/\partial |z||$  over |z| = 1 and  $|\zeta| = 1/2$  we obtain 1/3 which proves the lemma.

#### Proof of the theorem

We may assume without loss of generality that  $f_0$  has infinitely many zeros. Indeed, we can compose f with an automorphism of  $\mathbf{P}^n$ , for example replace  $f_0$  by  $f_0 + cf_1$ ,  $c \in \mathbf{C}$  and leave all other  $f_j$  unchanged. This transformation changes neither the n omitted hyperplanes nor the rate of growth of T(r, f) and multiplies the spherical derivative by a bounded factor.

Put  $u_j = \log |f_j|$ , and

$$u^* = \max_{1 \le j \le n} u_j.$$

Here and in what follows max denotes the pointwise maximum of subharmonic functions.

**Proposition 1.** Suppose that at some point  $z_1$  we have

$$u_m(z_1) = u_k(z_1) \ge u_j(z_1)$$

for some  $m \neq k$  and all  $j; m, k, j \in \{0, \dots, n\}$ . Then

$$||f'(z_1)|| \ge (n+1)^{-1} |\nabla u_m(z_1) - \nabla u_k(z_1)|.$$

Proof.

$$\|f'(z_1)\| \ge \frac{|f'_m(z_1)f_k(z_1) - f_m(z_1)f'_k(z_1)|}{|f_0(z_1)|^2 + \ldots + |f_n(z_1)|^2} \ge (n+1)^{-1} \left| \frac{f'_m(z_1)}{f_m(z_1)} - \frac{f'_k(z_1)}{f_k(z_1)} \right|,$$

and the conclusion of the proposition follows since  $|\nabla \log |f|| = |f'/f|$ .

**Proposition 2.** For every  $\epsilon > 0$ , we have

$$u(z) \le u^*(z) + K(2+\epsilon)^{\sigma+1}(n+1)|z|^{\sigma+1}$$

for all  $|z| > r_0(\epsilon)$ .

*Proof.* If  $u_0(z) \leq u^*(z)$  for all sufficiently large |z|, then there is nothing to prove. Suppose that  $u_0(a) > u^*(a)$ , and consider the largest disc B(a, R)centered at a where the inequality  $u_0(z) > u^*(z)$  persists. If  $z_0$  is the zero of the smallest modulus of  $f_0$  then  $R \leq |a| + |z_0| < (1 + \epsilon)|a|$  when |a| is large enough.

There is a point  $z_1 \in \partial B(a, R)$  such that  $u_0(z_1) = u^*(z_1)$ . This means that there is some  $k \in \{1, \ldots, n\}$  such that  $u_0(z_1) = u_k(z_1) \ge u_m(z_1)$  for all  $m \in \{1, \ldots, n\}$ . Applying Proposition 1 we obtain

$$|\nabla u_k(z_1) - \nabla u_0(z_1)| \le (n+1) ||f'(z_1)||.$$

Now  $u_0(z) > u^*(z) \ge u_k(z)$  for  $z \in B(a, R)$ , so we can apply Lemma 1 to  $v = u_0 - u_k$  in the disc B(a, R). This gives

$$u_0(a) - u_k(a) \le 2R |\nabla u_k(z_1) - \nabla u_0(z_1)| \le 2R(n+1) ||f'(z_1)||.$$

Now  $R < (1 + \epsilon)|a|$  and  $|z_1| \le (2 + \epsilon)|a|$ , so

$$u_0(a) \le u^*(a) + K(2+\epsilon)^{\sigma+1}(n+1)|a|^{\sigma+1},$$

and the result follows because  $u = \max\{u_0, u^*\} + O(1)$ .

Next we study the Riesz measure of the subharmonic function

$$u^* = \max\{u_1, \ldots, u_n\}.$$

We begin with maximum of two harmonic functions. Let  $u_1$  and  $u_2$  be two harmonic functions in  $\mathbf{C}$  of the form  $u_j = \operatorname{Re} P_j$  where  $P_j \neq 0$  are polynomials. Suppose that  $u_1 \neq u_2$ . Then the set  $E = \{z \in \mathbf{C} : u_1(z) = u_2(z)\}$  is a proper real-algebraic subset of  $\overline{\mathbf{C}}$  without isolated points. Apart from a finite set of ramification points, E consists of smooth curves. For every smooth point  $z \in E$ , we denote by J(z) the jump of the normal (to E) derivative of the function  $w = \max\{u_1, u_2\}$  at the point z. This jump is always positive and the Riesz measure  $\mu_w$  is given by the formula

$$d\mu_w = \frac{J(z)}{2\pi} |dz|,\tag{7}$$

which means that  $\mu_w$  is supported by E and has a density  $J(z)/2\pi$  with respect to the length element |dz| on E.

Now let  $E_{i,j} = \{z : u_i(z) = u_j(z) \ge u_k(z), 1 \le k \le n\}$ , and  $E = \bigcup E_{i,j}$ where the union is taken over all pairs  $1 \le i, j \le n$  for which  $u_i \ne u_j$ . Then E is a proper real semi-algebraic subset of  $\overline{\mathbf{C}}$ , and  $\infty$  is not an isolated point of E. For the elementary properties of semi-algebraic sets that we use here see, for example, [1, 5]. There exists  $r_0 > 0$  such that  $\Gamma = E \cap \{r_0 < |z| < \infty\}$ is a union of finitely many disjoint smooth simple curves,

$$\Gamma = \cup_{k=1}^{m} \Gamma_k.$$

This union coincides with the support of  $\mu_{u^*}$  in  $\{z : r_0 < |z| < \infty\}$ .

Consider a point  $z_0 \in \Gamma$ . Then  $z_0 \in \Gamma_k$  for some k. As  $\Gamma_k$  is a smooth curve, there is a neighborhood D of  $z_0$  which does not contain other curves  $\Gamma_j, j \neq k$  and which is divided by  $\Gamma_k$  into two parts,  $D_1$  and  $D_2$ . Then there exist i and j such that  $u^*(z) = u_i(z), z \in D_1$  and  $u^*(z) = u_j(z), z \in D_2$ , and  $u^*(z) = \max\{u_i(z), u_j(z)\}, z \in D$ . So the restriction of the Riesz measure  $\mu_{u^*}$  on D is supported by  $\Gamma_k \cap D$  and has density  $J(z)/(2\pi)$  where

$$|J(z)| = |\partial u_i / \partial n - \partial u_j / \partial n|(z) = |\nabla (u_i - u_j)|(z),$$

and  $\partial/\partial n$  is the derivation in the direction of a normal to  $\Gamma_k$ . Taking into account that  $u_j = \operatorname{Re} P_j$  where  $P_j$  are polynomials, we conclude that there exist positive numbers  $c_k$  and  $b_k$  such that

$$J(z)/(2\pi) = (c_k + o(1))|z|^{b_k}, \quad z \to \infty, \quad z \in \Gamma_k.$$
(8)

Let  $b = \max_k b_k$ , and among those curves  $\Gamma_k$  for which  $b_k = b$  choose one with maximal  $c_k$  (which we denote by  $c_0$ ). We denote this chosen curve by  $\Gamma_0$  and fix it for the rest of the proof.

**Proposition 3.** We have

$$b \leq \sigma$$
 and  $c_0 \leq 3 \cdot 4^{\sigma} K(n+1)$ .

*Proof.* We consider two cases.

Case 1. There is a sequence  $z_n \to \infty$ ,  $z_n \in \Gamma_0$  such that  $u_0(z_n) \leq u^*(z_n)$ . Then (1) and Proposition 1 imply that

$$J(z_n) \le (n+1)K|z_n|^{\sigma},$$

and comparison with (8) shows that  $b \leq \sigma$  and  $c_0 \leq K(n+1)/(2\pi)$ .

Case 2.  $u_0(z) > u^*(z)$  for all sufficiently large  $z \in \Gamma_0$ . Let *a* be a point on  $\Gamma_0$ ,  $|a| > 3r_0$ , and  $u_0(a) > u^*(a)$ . Let B(a, R) be the largest open disc centered at *a* in which the inequality  $u_0(z) > u^*(z)$  holds. Then

$$R \le |a| + O(1), \quad a \to \infty \tag{9}$$

because we assume that  $f_0$  has zeros, so  $u_0(z_0) = -\infty$  for some  $z_0$ .

In B(a, R) we consider the positive superharmonic function  $v = u_0 - u^*$ . Let us check that it satisfies the conditions of Lemma 2. The existence of a point  $z_1 \in \partial B(a, R)$  with  $v(z_1) = 0$  follows from the definition of B(a, R). The Riesz measure of  $\mu_v$  is estimated using (7), (8):

$$|\mu_v(B(a, R/2))| \ge |\mu_v(\Gamma_0 \cap B(a, R/2))| \ge c_0 R(|a| - R/2)^b.$$

Now Lemma 2 applied to v in B(a, R) implies that

$$|\nabla v(z_1)| \ge (c_0/3)(|a| - R/2)^b.$$
(10)

On the other hand (1) and Proposition 1 imply that

$$|\nabla v(z_1)| \le K(n+1)(|a|+R)^{\sigma}$$

Combining these two inequalities and taking (9) into account, we obtain  $b \leq \sigma$  and  $c_0 \leq 3 \cdot 4^{\sigma} K(n+1)$ , as required.

We denote

$$T^{*}(r) = \frac{1}{2\pi} \int_{-\pi}^{\pi} u^{*}(re^{i\theta})d\theta - u^{*}(0);$$

This is the characteristic of the "reduced curve"  $(f_1, \ldots, f_n)$ .

Proposition 4.

$$T^*(r) \le 6 \cdot 4^{\sigma} K \frac{n(n+1)^2}{\sigma+1}.$$

*Proof.* By Jensen's formula,

$$T^*(r) = \int_0^r \nu(t) \frac{dt}{t},$$

where  $\nu(t) = \mu_{u^*}(\{z : |z| \leq t\})$ . The number of curves  $\Gamma_k$  supporting the Riesz measure of  $u^*$  is easily seen to be at most  $2n(n-1)(\sigma+1)$ . The density of the Riesz measure  $\mu_{u^*}$  on each curve  $\Gamma_k$  is given by (8), where  $c_k \leq c_0$  and  $b_k \leq b$ , and the parameters  $c_0$  and b are estimated in Proposition 3. Combining all these data we obtain the result.

It remains to combine Propositions 2 and 4 to obtain the final result.
