ON THE 7TH ORDER ODE WITH SUBMAXIMAL SYMMETRY

MACIEJ DUNAJSKI AND VLADIMIR SOKOLOV

ABSTRACT. We find a general solution to the unique 7th order ODE admitting ten dimensional group of contact symmetries. The integral curves of this ODE are rational contact curves in $\mathbb{P}^3$ which give rise to rational plane curves of degree six. The moduli space of these curves is a real form of the homogeneous space $Sp(4)/SL(2)$.

The 7th order ODE

$$10(y^{(3)})^3 y^{(7)} - 70(y^{(3)})^2 y^{(4)} y^{(6)} - 49(y^{(3)})^2(y^{(5)})^2 + 280(y^{(3)})(y^{(4)})^2 y^{(5)} - 175(y^{(4)})^4 = 0, \tag{0.1}$$

where $y = y(x)$ and $y^{(k)} = d^k y/dx^k$ has recently appeared explicitly [11, 10, 4, 6] or implicitly [1] is several different contexts. It is the unique (up to contact transformations) equation admitting ten–dimensional algebra of contact symmetries, and the aim of this note is to show that its general solution is given by a degree six rational curve of the form

$$y^3 + \alpha(x)y^2 + \beta(x)y + \gamma(x) = 0, \tag{0.2}$$

where (α, β, γ) are a quadratic, a quartic, and a sextic respectively with the coefficients depending on seven parameters as in formula (0.11).

In fact the symmetry algebra of (0.1) was known to Lie [9] who also proved that this is the maximal algebra of contact vector fields on the plane. It is quite possible that equation (0.1) and its general solution were also known to Lie. We have been unable to find it in any of Lie's works, but we would be grateful to hear from anyone who has.

0.1. **Contact Lie algebras.** Let $U \subset \mathbb{R}^2$ be an open set and let $\mathbb{P}(T^*U)$ be a projectivised cotangent bundle with a contact one–form ω. A curve $\gamma \subset \mathbb{P}(TU)$ is called *contact* if $\omega|_\gamma = 0$. A contact transformation is a map $f : \mathbb{P}(TU) \to \mathbb{P}(TU)$ which takes contact curves into contact curves. Equivalently $f^*(\omega) = \lambda\omega$ for some function λ. Let (x, y) be the local coordinates on U and let z parametrise the fibers of $\mathbb{P}(TU)$, so that we can set $\omega = dy - zdx$. Consider a one parameter group of contact transformations. Close to the identity, this is characterised by a contact vector field X such that the contact condition $\mathcal{L}_X \omega = c\omega$ holds, where $\mathcal{L}_X = d(X \lrcorner) + X \lrcorner d$ is the Lie derivative and c is some function. The contact condition implies that locally there exist a function $H = H(x, y, z)$ such that

$$X_H = -(\partial_z H)\partial_x + (H - z\partial_z H)\partial_y + (\partial_x H + z\partial_y H)\partial_z. \tag{0.3}$$

If $H = a(x, y) + zb(x, y)$ then X_H generates a prolongation of a family of *point transformations* $f : U \to U$. Otherwise it generates a proper contact flow.

0.2. **The symmetry.** A remarkable result of Lie is that a maximum dimension of a Lie algebra of proper contact vector fields on the plane is ten. This maximal, ten–dimensional Lie algebra is generated by vector fields (0.3) corresponding to functions

$$1, x, x^2, y, z, xz, x^2z - 2xy, z^2, 2yz - xz^2, 4xyz - 4y^2 - x^2z^2. \tag{0.4}$$

This algebra is isomorphic to $\mathfrak{so}(5)$, or equivalently to $\mathfrak{sp}(4)$. The first seven generators correspond to prolonged point vector fields and the last three are the proper contact vector fields.

The algebra (0.4) generates all contact symmetries of equation (0.1): if $y(x)$ is a solution to (0.1) then so is $\tilde{y}(\tilde{x})$, where

$$\tilde{x} = \tilde{x}(x, y, z, c_i), \quad \tilde{y} = \tilde{y}(x, y, z, c_i), \quad \tilde{z} = \tilde{z}(x, y, z, c_i) = \frac{\partial_x \tilde{y} + z \partial_y \tilde{y}}{\partial_x \tilde{x} + z \partial_y \tilde{x}}, \quad \partial_z \tilde{y} = \tilde{z} \partial_z \tilde{x}$$

is the contact transformation generated by the vector fields (0.3) and $c_1, \ldots, c_{10}$ are parameters of this transformation. Equivalently, any of the generators (0.4) satisfies the linearisation of (0.1) when $z = y'$.

Another result of Lie [9] is that a maximal dimension of the contact symmetry algebra of an ODE of order $n > 3$ is $(n + 4)$, with maximal symmetry occurring if only if the ODE is contact equivalent to a trivial equation $y^{(n)} = 0$. Therefore equation (0.1) is of submaximal type [10] - it is not equivalent to the trivial equation and its symmetry algebra has the largest possible dimension. Up to the contact equivalence (0.1) is the unique 7th order ODE with this property.

0.3. **The solution.** We verify that the algebraic curve $y^2 + x(x - 1)^3 = 0$ solves (0.1). This curve is parametrised by

$$x(t) = \frac{1}{t^2 + 1}, \quad y(t) = -\frac{t^3}{(t^2 + 1)^2}.$$

The 7–dimensional subalgebra of (0.4) consisting of prolonged point symmetries integrates to

$$y \to c_4 y + c_1 + c_2 x + c_3 x^2, \quad x \to c_5 x + c_6, \quad \text{and} \quad y \to \frac{y}{(1 + c_7 x)^2}, \quad x \to \frac{x}{1 + c_7 x}. \quad (0.5)$$

Applying this group to the given solution yields the six parameter family of solutions to (0.1) given by a family of algebraic curves of degree four

$$(y + Q)^2 + P = 0 \tag{0.6}$$

where $Q = Q(x)$ is an arbitrary quadratic, and $P = P(x)$ is a quartic with one simple and one triple root. The curves in this family have two singularities: a cusp at $(x, y) = (x_0, -Q(x_0))$, where x_0 is the triple root of P and a point at ∞ of type $(2, 2, 2)$. Calculating the genus of curves in this family yields

$$\mathbf{g} = \frac{3 \cdot 2}{2} - 1 - 2 = 0$$

as the point at ∞ is not ordinary and has δ invariant equal to 4. Therefore the family is rational, and the rational parametrisation is given by

$$x(t) = \frac{b_5 + b_6 t^2}{b_0 + t^2}, \quad y(t) = \frac{b_4 t^4 + b_3 t^2 + b_2 t + b_1}{(b_0 + t^2)^2}.$$

The six parameters in (0.6) are algebraic expressions in the seven parameters $(b_0, \ldots, b_6)$ one of which is irrelevant and arises only in the parametrisation.

The family of curves (0.6) is not the general solution to (0.1) as it depends on six parameters rather than seven. To introduce the additional parameter, and construct the

general solution we use the contact transformation generated by[1] (0.3) with $H_8 = z^2$

$$\tilde{x}(t) = x(t) - 2bz(t), \quad \tilde{y}(t) = y(t) - bz(t)^2, \quad \tilde{z}(t) = z(t), \tag{0.7}$$

where

$$z(t) = \frac{\dot{y}(t)}{\dot{x}(t)} = \frac{(4b_4 b_0 - 2b_3)t^3 - 3b_2 t^2 + (2b_3 b_0 - 4b_1)t + b_2 b_0}{2(b_5 - b_0 b_6)(b_0 t + t^3)},$$

and $(b, b_0, \ldots b_6)$ are constant parameters. The relation (0.7) gives a seven–dimensional family of rational contact curves in $\mathbb{P}^3$. The symplectic group $Sp(4)$ acts on $\mathbb{P}^3$ and preserves the family (0.7). The symmetry group of any fixed rational curve in this family is $SL(2)$, and so the seven–dimensional space of solutions to (0.1) is the symmetric space $Sp(4)/SL(2)$. In the holomorphic category, a rational curve in $\mathbb{P}^3$ can be characterised by a normal bundle, which in our case is $N = \mathcal{O}(5) \oplus \mathcal{O}(5)$. The contact modification of the Kodaira theorem described in [2] can be applied to deduce that we have constructed a complete analytic family of contact curves: an infinitesimal contact deformation of any fixed curve in the family (0.7) also belongs to this family.

Alternatively, the general solution to (0.1) can be given by an implicit relation

$$u(x, y, z) = 0, \qquad v(x, y, z) = 0 \tag{0.8}$$

where (x, y, z) are coordinates on an open set in $\mathbb{P}^3$. Using (0.6) and (0.7) we find

$$u = (y + bz^2 + Q(X))^2 + P(X), \quad v = 4P(z + Q')^2 + (P')^2$$

where $Q = Q(X)$ is a quadratic, $P = P(X)$ is a quartic with one simple and one triple root, and $X = x + 2bz$. To find an explicit formula for $y(x)$ pick a real root z of the cubic $v = 0$, substitute this to $u = 0$ and solve the remaining quadratic for y. Alternatively we use the Bezout resultant to produce a planar curve birationaly equivalent to (0.8) by eliminating z between u and v. To obtain manageable formula consider (0.8) with $Q = 0$ and $P = X(X - 1)^3$, and find the resultant of u and v. This resultant factorises into two terms, each giving a rational curve of degree six. We choose one of these two curves[2]

$$\begin{aligned}
&\left(64\, b + 1024\, b^3\right) y^3 + \left(\left(768\, b^2 + 16\right) x^2 - 768\, xb^2 + 288\, b^2\right) y^2 \\
&+ \left(264\, x^2 b - 108\, b^3 + 192\, x^4 b - 72\, xb - 384\, x^3 b\right) y \\
&+ \left(48\, x^4 - 27\, b^2 + 54\, xb^2 - 16\, x^3 - 27\, x^2 b^2 - 48\, x^5 + 16\, x^6\right) = 0.
\end{aligned} \tag{0.9}$$

This curve does not belong to the class (0.6): it has two cusps and one non-ordinary singularity at ∞ whereas (0.6) has one cusp (apart from the singularity at ∞). The curve (0.9) possesses the following property: its discriminant is a cube of a quartic $Q(x)$ in x with two real roots. These roots correspond to the positions of the finite cusps, as in Figure 1. For any such curve (0.2) the cross-ratio ρ of the roots of Q is an invariant with respect to transformations (0.5). It is possible to verify that for (0.9) we have $\rho = \varepsilon$, where $\varepsilon = \exp\left(\frac{i\pi}{3}\right)$. To bring the curve (0.9) to a canonical form we first set the coefficient of y^2

---

[1]For completeness we present the contact transformations generated by (0.3) with $H_9 = 2yz - xz^2$ and $H_{10} = 4xyz - 4y^2 - x^2 z^2$ respectively. They are given by

$$\tilde{x} = \frac{x(1 + c_9 z) - 2c_9 y}{1 - c_9 z}, \quad \tilde{y} = \frac{y(1 - 2c_9 z) + c_9 x z^2}{(1 - c_9 z)^2}, \quad \tilde{z} = \frac{z}{1 - c_9 z}, \quad \text{and}$$

$$\tilde{x} = \frac{x}{1 + 4c_{10} y - 2c_{10} xz}, \quad \tilde{y} = \frac{y + 4c_{10} y^2 - 4c_{10} xyz + c_{10} x^2 z^2}{(1 + 4c_{10} y - 2c_{10} xz)^2}, \quad \tilde{z} = \frac{z}{1 + 4c_{10} y - 2c_{10} xz}$$

where $c_9, c_{10} \in \mathbb{R}$. The degree four curve (0.6) can be obtained applying H_9 and the point transformations to the trivial solution $y = x^2$.

[2]The second curve is not a solution to the ODE (0.1). Its singular points consist of an irregular point at ∞ and two finite double points. The discriminant is proportional to $Q(x)R(x)^2$ where $Q(x)$ is a quartic corresponding to the discriminant of (0.9), and $R(x)$ is another quartic.

FIGURE 1. Curve (0.9) with $b = 1/2$ and curve (0.6) with $Q = 0, P = x(x-1)^3$.
to zero by a transformation of the form $y \to y + c_1 + c_2 x + c_3 x^2$. After that the remaining Möbius transformations can be used to set $Q(x) = x(x-1)(x-\rho)$. This, up to scaling of y, yields

$$y^3 - 3y\left(x - (1-\varepsilon)\right)\left(x - (1+\varepsilon)\right)\left(x - \frac{1}{3}(1+\varepsilon)\right)\left(x - (-1+\varepsilon)\right) +$$

$$2\left(x - (1-i\varepsilon)\right)\left(x - (1+i\varepsilon)\right)\left(x - (i-i\varepsilon)\right)\left(x - (-i+i\varepsilon)\right)\left(x - (i+\varepsilon)\right)\left(x - (-i+\varepsilon)\right) = 0.$$

The discriminant $Q(x)$ of this curve is proportional to $x^3(x-1)^3(x-\varepsilon)^3$.

Using this complex canonical form, we easily can find a real one. To do that we find four roots of the sextic in x in the complex canonical form such that their cross-ratio is -1. Using the Möbius transformations, we move these roots to $\pm 1 \pm i$. The result (up to scaling of x and y) is given by

$$y^3 + 3(3x^4 - 6x^2 - 1)y + 12x(3x^4 + 1) = 0 \qquad (0.10)$$

which can be parametrised by

$$x(t) = \frac{t(t^2 - 3)}{3(t^2 + 1)}, \quad y(t) = -\frac{4t(t^4 + 3)}{3(t^2 + 1)^2}.$$

To get the general solution for 7th order ODE (0.1) we apply the point transformations (0.5) to (0.10). The resulting degree six rational curve of the form (0.2) is given by

$$\left(c_4 y + c_1 + c_2 x + c_3 x^2\right)^3 \qquad (0.11)$$
$$+ 3\left(3\left(c_5 x + c_6\right)^4 - 6\left(c_5 x + c_6\right)^2\left(1 - c_7 x\right)^2 - \left(1 - c_7 x\right)^4\right)\left(c_4 y + c_1 + c_2 x + c_3 x^2\right)$$
$$+ 12\left(c_5 x + c_6\right)\left(3\left(c_5 x + c_6\right)^4\left(1 - c_7 x\right) + \left(1 - c_7 x\right)^5\right) = 0.$$

0.4. **Conclusions.** We have found the general solution of the 7th order ODE (0.1). This equation is submaximal as its symmetry algebra is ten–dimensional, wheres the algebra of the trivial 7th order ODE is eleven–dimensional. The general solution to (0.1) is given by the seven dimensional orbit of the point transformations (0.5) acting on the canonical solution (0.10). There also exists a six–dimensional submanifold in the space of solutions given by degree four curves (0.6). For each contact transformations generated by H_8, H_9 and H_{10} in (0.4) there exists a point transformation such that the composition of the two fixes (0.10). This gives a stabiliser $SL(2)$ of (0.10) and finally the solution space $Sp(4)/SL(2)$.

The analogous, submaximal 5th order ODE characterises conics in $\mathbb{RP}^2$. In the inhomogeneous coordinates (x, y) the five parameter family of conics is

$$y^2 = c_1 x^2 + c_2 xy + c_3 y + c_4 x + c_5.$$

Eliminating the parameters $(c_1, \ldots, c_5)$ between this equation and its fourth derivatives and substituting in the fifth derivative yields the ODE

$$9(y^{(2)})^2 y^{(5)} - 45 y^{(2)} y^{(3)} y^{(4)} + 40(y^{(3)})^3 = 0.$$

This construction goes back to Halphen [8] who wrote the equation as $((y^{(2)})^{-2/3})^{(3)} = 0$.

The seven–dimensional space of solutions M to (0.1) carries a $GL(2, \mathbb{R})$ structure in the sense of [5, 4]: TM has a pointwise identification with a vector space of homogeneous degree six polynomials in two variables. The five Wünschmann–Doubrov–Wilczynski invariants vanish on the ODE (0.1) which implies [3] that the linearisation of (0.1) is equivalent to a trivial ODE $\delta y^{(7)} = 0$. Moreover [6], M also admits a conformal structure of signature $(3, 4)$. The null vectors of this structure correspond to the six order polynomials

$$a_1 x^6 + 6a_2 x^5 + 15a_3 x^4 + 20a_4 x^3 + 15a_5 x^2 + 6a_6 x + a_7$$

with vanishing quadratic invariant [7]

$$a_1 a_7 - 6a_2 a_6 + 15a_3 a_5 - 10a_4^2.$$

In [6] it was shown that the conformal structure associated to (0.1) contains a metric with weak holonomy $\tilde{G}_2$: there exists a three form ϕ on M such that

$$d\phi = \Lambda * \phi, \quad d * \phi = 0$$

where Λ is a constant, and $*$ is the Hodge operator. Taking an analytic continuation of this structure to the Riemannian signature yields the homology seven–sphere $M = SO(5)/SO(3)$ with its canonical weak G_2 structure originally constructed by Bryant [1].
