

**AN INTERACTING PARTICLES MODEL  
AND  
A PIERI-TYPE FORMULA FOR THE ORTHOGONAL GROUP**

MANON DEFOSSEUX

**ABSTRACT.** We introduce a new interacting particles model with blocking and pushing interactions. Particles evolve on the positive line jumping on their own volition rightwards or leftwards according to geometric jumps with parameter  $q \in ]0, 1[$ . We show that the model involves a Pieri-type formula for the orthogonal group. We prove that the two extreme cases -  $q = 0$  and  $q = 1$  - lead respectively to a random tiling model studied in [1] and a random matrix model considered in [4].

1. INTRODUCTION

In [1] A. Borodin and J. Kuan consider a random tiling model with a wall which is related to the Plancherel measure for the orthogonal group and thus to representation theory of this group. Similar connection holds for the interacting particles model and the random matrix model considered in [4]. The aim of this paper is to establish a direct link between the random tiling model on one side and the interacting particles model or the random matrix model on the other side. For this we consider an interacting particle model depending on a parameter and show that these models correspond to different parameter values. The paper is organized as follows. Definition of the set of Gelfand-Tsetlin patterns for the orthogonal group is recalled in section 2. Section 3 is devoted to the description of the particles model. We recall in section 4 the description of an interacting particle model equivalent to the random tiling model studied in [1]. Models considered in that paper involve Markov kernels which can be obtained with the help of a Pieri-type formula for the orthogonal group. These Markov kernels are constructed in section 5 after recalling some elements of representation theory. We describe the matrix model related to our particles model in section 6. Results are stated in section 7 and proved in section 8.

*Acknowledgments:* The author would like to thank Alexei Borodin for its suggestions and helpful explanations.

2. GELFAND-TSETLIN PATTERNS

Let  $n$  be a positive integer. For  $x, y \in \mathbb{R}^n$  such that  $x_n \leq \dots \leq x_1$  and  $y_n \leq \dots \leq y_1$ , we write  $x \preceq y$  if  $x$  and  $y$  are interlaced, i.e.

$$x_n \leq y_n \leq x_{n-1} \leq \dots \leq x_1 \leq y_1.$$

When  $x \in \mathbb{R}^n$  and  $y \in \mathbb{R}^{n+1}$  we add the relation  $y_{n+1} \leq x_n$ . We denote  $|x|$  the vector whose components are the absolute values of those of  $x$ .

**Definition 2.1.** Let  $k$  be a positive integer.

(1) We denote by  $GT_k$  the set of Gelfand-Tsetlin patterns defined by

$$GT_k = \{(x^1, \dots, x^k) : x^i \in \mathbb{N}^{j-1} \times \mathbb{Z} \text{ when } i = 2j - 1, \\ x^i \in \mathbb{N}^j \text{ when } i = 2j, |x^{i-1}| \preceq |x^i|, 1 \leq i \leq k\}.$$

(2) If  $x = (x^1, \dots, x^k)$  is a Gelfand-Tsetlin pattern,  $x^i$  is called the  $i^{\text{th}}$  line of  $x$  for  $i \in \{1, \dots, k\}$ .

(3) For  $\lambda \in \mathbb{Z}^{\lfloor \frac{k+1}{2} \rfloor}$  the subset of Gelfand-Tsetlin patterns having a  $k^{\text{th}}$  line equal to  $\lambda$  is denoted by  $GT_k(\lambda)$  and its cardinal is denoted by  $s_k(\lambda)$ .

Usually, a Gelfand Tsetlin pattern is represented by a triangular array as indicated at figure 1 for  $k = 2r$ .

$$\begin{array}{cccccccc} & & & & x_1^1 & & & & \\ & & & & -x_1^2 & & x_1^2 & & \\ & & & & -x_1^3 & & x_2^3 & & x_1^3 \\ & & & -x_1^4 & & -x_2^4 & & x_2^4 & & x_1^4 \\ & & & & & \dots & & \dots & & \\ & & -x_1^{2r-1} \dots & & -x_{r-1}^{2r-1} & & x_r^{2r-1} & & x_{r-1}^{2r-1} & \dots & x_1^{2r-1} \\ -x_1^{2r} & & \dots & & -x_r^{2r} & & x_r^{2r} & & \dots & & x_1^{2r} \end{array}$$

FIGURE 1. A Gelfand-Tsetlin pattern of  $GT_{2r}$ .

### 3. AN INTERACTING PARTICLES MODEL WITH EXPONENTIAL JUMPS

Let  $k$  be a positive integer. In this section we construct a process  $(X(t))_{t \geq 0}$  evolving on the set  $GT_k$  of Gelfand-Tsetlin patterns with non negative valued components. This process can be viewed as an interacting particles model. For this, we associate to a Gelfand-Tsetlin pattern  $x = (x^1, \dots, x^k)$ , a configuration of particles on the integer lattice  $\mathbb{Z}^2$  putting one particle labeled by  $(i, j)$  at point  $(k - i, x_j^i)$  of  $\mathbb{Z}^2$  for  $i \in \{1, \dots, k\}$ ,  $j \in \{1, \dots, \lfloor \frac{i+1}{2} \rfloor\}$ . Several particles can be located at the same point. In the sequel we identify each particles with its corresponding component. Let  $q \in ]0, 1[$ . Consider two independent families

$$\left(\xi_j^i\left(n + \frac{1}{2}\right)\right)_{i=1, \dots, k, j=1, \dots, \lfloor \frac{i+1}{2} \rfloor; n \geq 0}, \quad \text{and} \quad \left(\xi_j^i(n)\right)_{i=1, \dots, k, j=1, \dots, \lfloor \frac{i+1}{2} \rfloor; n \geq 1},$$

of identically distributed independent random variables such that

$$\mathbb{P}\left(\xi_1^1\left(\frac{1}{2}\right) = x\right) = \mathbb{P}\left(\xi_1^1(1) = x\right) = q^x(1 - q), \quad x \in \mathbb{N},$$

and the markov Kernel  $R$  on  $\mathbb{N}$  defined by

$$R(x, y) = \begin{cases} \frac{1-q}{1+q}(q^{|x-y|} + q^{x+y}) & \text{if } y \in \mathbb{N}^* \\ \frac{1-q}{1+q}q^x & \text{otherwise,} \end{cases}$$

for  $x \in \mathbb{N}$ . Actually for  $x \in \mathbb{N}$  the probability measure  $R(x, \cdot)$  on  $\mathbb{N}$  is the law of the random variable  $|x + \xi_1^1(1) - \xi_1^1(\frac{1}{2})|$ .

Particles evolve as follows. At time 0 all particles are at zero, i.e.  $X(0) = 0$ . All particles, except those labeled by  $(2l - 1, l)$  for  $l \in \{1, \dots, \lfloor \frac{k+1}{2} \rfloor\}$ , try to jump to

the left at times  $n + \frac{1}{2}$  and to the right at times  $n$ ,  $n \in \mathbb{N}$ . For  $l \in \{1, \dots, [\frac{k+1}{2}]\}$ , particle labeled by  $(2l - 1, l)$  jumps on its own volition at times  $n$  only. Suppose that at time  $n$  there is one particle at point  $(k - i, X_j^i(n))$  of  $\mathbb{Z}^2$ , for  $i = 1, \dots, k$ ,  $j = 1, \dots, [\frac{i+1}{2}]$ . Positions of particles are updated recursively as follows (see also figure 2).

At time  $n + 1/2$  : All particles except particles  $X_l^{2l-1}(n)$  for  $l \in \{1, \dots, [\frac{k+1}{2}]\}$ , try to jump to the left one after another in the lexicographic order pushing the particles in order to stay in the set of Gelfand-Tsetlin patterns and being blocked by the initial configuration  $X(n)$  of the particles. Let us indicate how the first three lines are updated at time  $n + \frac{1}{2}$ .

- Particle  $X_1^1(n)$  doesn't move. We let

$$X_1^1(n + \frac{1}{2}) = X_1^1(n).$$

- Particle  $X_1^2(n)$  tries to jump to the left according to a geometric jump. It is blocked by  $X_1^1(n)$ . If it is necessary it pushes  $X_2^3(n)$  to an intermediate position denoted by  $\tilde{X}_2^3(n)$ , i.e.

$$X_1^2(n + \frac{1}{2}) = \max(X_1^1(n), X_1^2(n) - \xi_1^2(n + \frac{1}{2}))$$

$$\tilde{X}_2^3(n) = \min(X_2^3(n), X_1^2(n + \frac{1}{2}))$$

- Particle  $X_1^3(n)$  tries to move to the left according to a geometric jump being blocked by  $X_1^2(n)$  :

$$X_1^3(n + \frac{1}{2}) = \max(X_1^2(n), X_1^3(n) - \xi_1^3(n + \frac{1}{2})).$$

Particle  $\tilde{X}_2^3(n)$  doesn't move. We let

$$X_2^3(n + \frac{1}{2}) = \tilde{X}_2^3(n).$$

Suppose now that rows 1 through  $l - 1$  have been updated for some  $l > 1$ . Then particles  $X_1^l(n), \dots, X_{[\frac{l+1}{2}]}^l(n)$  of line  $l$  are pushed to intermediate positions

$$\tilde{X}_i^l(n) = \min(X_i^l(n), X_{i-1}^{l-1}(n + \frac{1}{2})), i \in \{1, \dots, [\frac{l+1}{2}]\}.$$

with the convention  $X_0^{l-1}(n + \frac{1}{2}) = +\infty$ . Then particles  $\tilde{X}_1^l(n), \dots, \tilde{X}_{[\frac{l}{2}]}^l(n)$  try to jump to the left according to geometric jump being blocked as follows by the initial position  $X(n)$  of the particles. For  $i = 1, \dots, [\frac{l}{2}]$ ,

$$X_i^l(n + \frac{1}{2}) = \max(X_i^{l-1}(n), \tilde{X}_i^l(n) - \xi_i^l(n + \frac{1}{2})).$$

When  $l$  is odd, particle  $\tilde{X}_{\frac{l+1}{2}}^l(n)$  doesn't move and we let

$$X_{\frac{l+1}{2}}^l(n + \frac{1}{2}) = \tilde{X}_{\frac{l+1}{2}}^l(n).$$

At time  $n + 1$  : All particles except particles  $X_l^{2l-1}(n + \frac{1}{2})$  for  $l \in \{1, \dots, [\frac{k+1}{2}]\}$ , try to jump to the right one after another in the lexicographic order pushing particles in order to stay in the set of Gelfand-Tsetlin patterns and being blocked by the

initial configuration  $X(n + \frac{1}{2})$  of the particles. The first three lines are updated as follows.

- Particle  $X_1^1(n + \frac{1}{2})$  moves according to the law  $R(X_1^1(n + \frac{1}{2}), \cdot)$  pushing  $X_1^2(n + \frac{1}{2})$  to an intermediate position  $\tilde{X}_1^2(n + \frac{1}{2})$  :

$$X_1^1(n+1) = |X_1^1(n + \frac{1}{2}) + \xi_1^1(n+1) - \xi_1^1(n + \frac{1}{2})|$$

$$\tilde{X}_1^2(n + \frac{1}{2}) = \max(X_1^2(n + \frac{1}{2}), X_1^1(n+1))$$

- Particle  $\tilde{X}_1^2(n + \frac{1}{2})$  jumps to the right according to a geometric jump pushing  $X_1^3(n + \frac{1}{2})$  to an intermediate position  $\tilde{X}_1^3(n + \frac{1}{2})$ , i.e.

$$X_1^2(n+1) = \tilde{X}_1^2(n + \frac{1}{2}) + \xi_1^2(n+1)$$

$$\tilde{X}_1^3(n + \frac{1}{2}) = \max(X_1^3(n + \frac{1}{2}), X_1^2(n+1))$$

- Particle  $X_2^3(n + \frac{1}{2})$  tries to move according to the law  $R(X_1^1(n + \frac{1}{2}), \cdot)$ . It is blocked by  $X_1^2(n + \frac{1}{2})$ . Particle  $\tilde{X}_1^3(n + \frac{1}{2})$  moves to the right according to a geometric jump. That is

$$X_2^3(n+1) = \max(|X_2^3(n + \frac{1}{2}) + \xi_2^3(n+1) - \xi_2^3(n + \frac{1}{2})|, X_1^2(n + \frac{1}{2}))$$

$$X_1^3(n+1) = \tilde{X}_1^3(n + \frac{1}{2}) + \xi_1^3(n+1)$$

Suppose rows 1 through  $l - 1$  have been updated for some  $l > 1$ . Then particles of line  $l$  are pushed to intermediate positions

$$\tilde{X}_i^l(n + \frac{1}{2}) = \max(X_i^{l-1}(n+1), X_i^l(n + \frac{1}{2})), i \in \{1, \dots, [\frac{l+1}{2}]\},$$

with the convention  $X_{\frac{l+1}{2}}^{l-1}(n+1) = 0$  when  $l$  is odd. Then particles  $\tilde{X}_1^l(n + \frac{1}{2}), \dots, \tilde{X}_{[\frac{l}{2}]}^l(n + \frac{1}{2})$  try to jump to the right according to geometric jump being blocked by the initial position of the particles as follows. For  $i = 1, \dots, [\frac{l}{2}]$ ,

$$X_i^l(n+1) = \min(X_{i-1}^{l-1}(n + \frac{1}{2}), \tilde{X}_i^l(n + \frac{1}{2}) + \xi_i^l(n+1)).$$

When  $l$  is odd, particle  $X_{\frac{l+1}{2}}^l(n + \frac{1}{2})$  is updated as follows.

$$X_{\frac{l+1}{2}}^l(n+1) = \min(|X_{\frac{l+1}{2}}^l(n + \frac{1}{2}) + \xi_{\frac{l+1}{2}}^l(n+1) - \xi_{\frac{l+1}{2}}^l(n + \frac{1}{2})|, X_{\frac{l-1}{2}}^{l-1}(n + \frac{1}{2}))$$

#### 4. AN INTERACTING PARTICLES MODEL WITH EXPONENTIAL WAITING TIMES

In this section we describe an interacting particles model on  $\mathbb{Z}^2$  where particles try to jump by one rightwards or leftwards after exponentially distributed waiting times. The evolution of the particles is described by a random process  $(Y(t))_{t \geq 0}$  on the set  $GT_k$  of Gelfand-Tsetlin patterns with non negative valued components. As in the previous model, at time  $t \geq 0$  there is one particle labeled by  $(i, j)$  at point  $(k - i, Y_j^i(t))$  of the integer lattice, for  $i = 1, \dots, k$ ,  $j = 1, \dots, [\frac{k+1}{2}]$ . Every particles try to jump to the left or to the right by one after independent exponentially distributed waiting time with mean 1. Particles are pushed and blocked according

to the same rules as previously. That is when particle labeled by  $(i, j)$  wants to jump to the right at time  $t \geq 0$  then

- (1) if  $i, j \geq 2$  and  $Y_j^i(t^-) = Y_{j-1}^{i-1}(t^-)$  then particles don't move and  $Y(t) = Y(t^-)$ .
- (2) else particles  $(i, j), (i+1, j), \dots, (i+l, j)$  jump to the right by one for  $l$  the largest integer such that  $Y_j^{i+l}(t^-) = Y_j^i(t^-)$  i.e.

$$X_j^i(t) = X_j^i(t^-) + 1, \dots, X_j^{i+l}(t) = X_j^{i+l}(t^-) + 1.$$

When particle labeled by  $(i, j)$  wants to jump to the left at time  $t \geq 0$  then

- (1) if  $i$  is odd,  $j = (i+1)/2$  and  $X_j^i(t^-) = 0$  then particle labeled by  $(i, j)$  is reflected by 0 and everything happens as described above when this particle try to jump to the right by one.
- (2) if  $i$  is odd,  $j = (i+1)/2$  and  $X_j^i(t^-) \geq 1$  then  $X_j^i(t) = X_j^i(t^-) - 1$ .
- (3) if  $i$  is even or  $j \neq (i+1)/2$ , and  $X_j^i(t^-) = X_j^{i-1}(t^-)$  then particles don't move.
- (4) if  $i$  is even or  $j \neq (i+1)/2$ , and  $X_j^i(t^-) > X_j^{i-1}(t^-)$  then particles  $(i, j), (i+1, j+1), \dots, (i+l, j+l)$  jump to the left by one for  $l$  the largest integer such that  $Y_{j+l}^{i+l}(t^-) = Y_j^i(t^-)$ . Thus

$$X_j^i(t) = X_j^i(t^-) - 1, \dots, X_{j+l}^{i+l}(t) = X_{j+l}^{i+l}(t^-) - 1.$$

This random particles model is equivalent to a random tiling model with a wall, as it has been explained in detail in [1].

## 5. MARKOV KERNEL ON THE SET OF IRREDUCIBLE REPRESENTATIONS OF THE ORTHOGONAL GROUP

When a finite dimensionnal representation  $V$  of a group  $G$  is completely reducible, there is a natural way that we'll recall later in our particular case to associate to this decomposition a probability measure on the set of irreducible representations of  $G$ . Theorem 7.1 claims that the process  $(X^k(t), t \geq 0)$  is Markovian. It occurs that the transition probabilities of this process can be obtained in that manner. Actually we recover them considering decomposition into irreducible components of tensor products of particular irreducible representations of the special orthogonal group.

Let  $d$  be an integer greater than 2. Let us recall some usual properties of the finite dimensional representations of the compact group  $SO(d)$  of  $d \times d$  orthogonal matrices with determinant equal to 1 (see for instance [5] for more details). The set of finite dimensional representations of  $SO(d)$  is indexed by the set

$$\{\lambda \in \mathbb{R}^r : 2\lambda_r \in \mathbb{N}, \lambda_i - \lambda_{i+1} \in \mathbb{N}, i = 1, \dots, r-1\},$$

when  $d = 2r + 1$  and by the set

$$\{\lambda \in \mathbb{R}^r : \lambda_{r-1} + \lambda_r \in \mathbb{N}, \lambda_i - \lambda_{i+1} \in \mathbb{N}, i = 1, \dots, r-1\},$$

when  $d = 2r$ . Actually we are only interested with representations indexed by a subset  $\mathcal{W}_d$  of these sets define by

$$\mathcal{W}_d = \{\lambda \in \mathbb{R}^r : \lambda_r \in \mathbb{N}, \lambda_i - \lambda_{i+1} \in \mathbb{N}, i = 1, \dots, r-1\},$$

when  $d = 2r + 1$  and

$$\mathcal{W}_d = \{\lambda \in \mathbb{R}^r : \lambda_r \in \mathbb{Z}, \lambda_{r-1} + \lambda_r \in \mathbb{N}, \lambda_i - \lambda_{i+1} \in \mathbb{N}, i = 1, \dots, r-1\},$$

when  $d = 2r$ . For  $\lambda \in \mathcal{W}_d$ , using standard notations, we denote by  $V_\lambda$  the so called irreducible representation with highest weight  $\lambda$  of  $SO(d)$ . The subset of  $\mathcal{W}_d$  whose elements have non negative components is denoted by  $\mathcal{W}_d^+$ .

Let  $m$  be an integer and  $\lambda$  an element of  $\mathcal{W}_d$ . Consider the irreducible representations  $V_\lambda$  and  $V_{\gamma_m}$  of  $SO(d)$ , with  $\gamma_m = (m, 0, \dots, 0)$ . The decomposition of the tensor product  $V_\lambda \otimes V_{\gamma_m}$  into irreducible components is given by a Pieri-type formula for the orthogonal group. It has been recalled in [3]. We have

$$(1) \quad V_\lambda \otimes V_{\gamma_m} = \bigoplus_{\beta} M_{\lambda, \gamma_m}(\beta) V_\beta,$$

where the direct sum is over all  $\beta \in \mathcal{W}_d$  such that

- when  $d = 2r + 1$ , there exists an integer  $s \in \{0, 1\}$  and  $c \in \mathbb{N}^r$  which satisfy

$$\begin{cases} c \preceq \lambda, & c \preceq \beta \\ \sum_{i=1}^r (\lambda_i - c_i + \beta_i - c_i) + s = m, \end{cases}$$

$s$  being equal to 0 if  $c_r = 0$ . In addition, the multiplicity  $M_{\lambda, \gamma_m}(\beta)$  of the irreducible representation with highest weight  $\beta$  is the number of  $(c, s) \in \mathbb{N}^r \times \{0, 1\}$  satisfying these relations.

- when  $d = 2r$ , there exists  $c \in \mathbb{N}^{r-1}$  which verifies

$$\begin{cases} c \preceq |\lambda|, & c \preceq |\beta| \\ \sum_{k=1}^{r-1} (\lambda_k - c_k + \beta_k - c_k) + |\lambda_r - \mu_r| = m. \end{cases}$$

In addition, the multiplicity  $M_{\lambda, \gamma_m}(\beta)$  of the irreducible representation with highest weight  $\beta$  is the number of  $c \in \mathbb{N}^{r-1}$  satisfying these relations.

Let us consider a family  $(\mu_m)_{m \geq 0}$  of Markov kernels on  $\mathcal{W}_d$  defined by

$$\mu_m(\lambda, \beta) = \frac{\dim(V_\lambda)}{\dim(V_\beta) \dim(V_{\gamma_m})} M_{\lambda, \gamma_m}(\beta),$$

for  $\lambda, \beta \in \mathcal{W}_d$  and  $m \geq 0$ . It is known that for  $\lambda \in \mathcal{W}_d$  the dimension of  $V_\lambda$  is given by  $s_{d-1}(\lambda)$ . Thus

$$\mu_m(\lambda, \beta) = \frac{s_{d-1}(\lambda)}{s_{d-1}(\beta) s_{d-1}(\gamma_m)} M_{\lambda, \gamma_m}(\beta).$$

Let  $\xi_1, \dots, \xi_d$  be independent geometric random variables with parameter  $q$  and  $\epsilon$  a Bernoulli random variable such that

$$\mathbb{P}(\epsilon = 1) = 1 - \mathbb{P}(\epsilon = 0) = \frac{q}{1 + q}.$$

Consider a random variable  $T$  on  $\mathbb{N}$  defined by

$$T = \sum_{i=1}^{d-1} \xi_i + \epsilon,$$

when  $d = 2r + 1$  and

$$T = |\xi_1 - \xi_2| + \sum_{i=3}^d \xi_i,$$

when  $d = 2r$ .

**Lemma 5.1.** *The law of  $T$  is a measure  $\nu$  on  $\mathbb{N}$  defined by*

$$\nu(m) = \frac{1}{1+q}(1-q)^{d-1}q^m s_{d-1}(\gamma_m), \quad m \in \mathbb{N}.$$

*Proof.* When  $d = 2r + 1$ , for  $m = 0$  the property is true. For  $m \geq 1$

$$\begin{aligned} \mathbb{P}(T = m) &= \frac{q}{1+q} \mathbb{P}\left(\sum_{i=1}^{d-1} \xi_i = m-1\right) + \frac{1}{1+q} \mathbb{P}\left(\sum_{i=1}^{d-1} \xi_i = m\right) \\ &= \frac{1}{1+q} (1-q)^{d-1} q^m \text{Card}\{(k_1, \dots, k_{d-1}) \in \mathbb{N}^{d-1} : \sum_{i=1}^{d-1} k_i \in \{m-1, m\}\} \\ &= \frac{1}{1+q} (1-q)^{d-1} q^m \sum_{(k_1, \dots, k_{d-1}) \in \mathbb{N}^{d-1} : \sum_{i=1}^{d-1} k_i = m} (2\mathbf{1}_{k_1 \geq 1} + \mathbf{1}_{k_1 = 0}) \\ &= \frac{1}{1+q} (1-q)^{d-1} q^m s_{d-1}(\gamma_m). \end{aligned}$$

So the lemma is proved in the odd case. Moreover

$$\mathbb{P}(|\xi_1 - \xi_2| = k) = \begin{cases} 2\frac{1-q}{1+q}q^k & \text{if } k \geq 1, \\ \frac{1-q}{1+q} & \text{otherwise.} \end{cases}$$

Thus when  $d = 2r$ ,

$$\begin{aligned} \mathbb{P}(T = m) &= \frac{1}{1+q} (1-q)^{d-1} q^m \sum_{(k_1, \dots, k_{d-1}) \in \mathbb{N}^{d-1} : \sum_{i=1}^{d-1} k_i = m} (2\mathbf{1}_{k_1 \geq 1} + \mathbf{1}_{k_1 = 0}) \\ &= \frac{1}{1+q} (1-q)^{d-1} q^m s_{d-1}(\gamma_m). \end{aligned}$$

□

Lemma 5.1 implies in particular that the measure  $\nu$  is a probability measure. Thus one defines a Markov kernel  $P_d$  on  $\mathcal{W}_d$  letting

$$(2) \quad P_d(\lambda, \beta) = \sum_{m=0}^{+\infty} \mu_m(\lambda, \beta) \nu(m),$$

for  $\lambda, \beta \in \mathcal{W}_d$ .

**Proposition 5.2.** *For  $\lambda, \beta \in \mathcal{W}_d$ ,*

$$P_d(\lambda, \beta) = \sum_{c \in \mathbb{N}^r : c \leq \lambda, \beta} (1-q)^{d-1} \frac{s_{d-1}(\beta)}{s_{d-1}(\lambda)} q^{\sum_{i=1}^r (\lambda_i + \beta_i - 2c_i)} (1_{c_r > 0} + \frac{1_{c_r = 0}}{1+q})$$

when  $d = 2r + 1$  and

$$P_d(\lambda, \beta) = \sum_{c \in \mathbb{N}^{r-1} : c \leq |\lambda|, |\beta|} (1-q)^{d-1} \frac{s_{d-1}(\beta)}{s_{d-1}(\lambda)} q^{\sum_{i=1}^{r-1} (\lambda_i + \beta_i - 2c_i) + |\lambda_r - \beta_r|}$$

when  $d = 2r$ .

*Proof.* Proposition follows immediately from the tensor product rules recalled for the decomposition (1). □

## 6. RANDOM MATRICES

Let us denote by  $\mathcal{M}_{d,d'}$  the set of  $d \times d'$  real matrices. A standard Gaussian variable on  $\mathcal{M}_{d,d'}$  is a random variable having a density with respect to the Lebesgue measure on  $\mathcal{M}_{d,d'}$  equal to

$$M \in \mathcal{M}_{d,d'} \mapsto \frac{1}{a^{d'} \sqrt{2\pi}} \exp\left(-\frac{1}{2} \operatorname{tr}(MM^*)\right).$$

We write  $\mathcal{A}_d$  for the set  $\{M \in \mathcal{M}_{d,d} : M + M^* = 0\}$  of antisymmetric  $d \times d$  real matrices, and  $i\mathcal{A}_d$  for the set  $\{iM : M \in \mathcal{A}_d\}$ . Since a matrix in  $i\mathcal{A}_d$  is Hermitian, it has real eigenvalues  $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_d$ . Moreover, antisymmetry implies that  $\lambda_{d-i+1} = -\lambda_i$ , for  $i = 1, \dots, [d/2] + 1$ , in particular  $\lambda_{[d/2]+1} = 0$  when  $d$  is odd. Consider the subset  $\mathcal{C}_d$  of  $\mathbb{R}_+^{[d/2]}$  defined by

$$\mathcal{C}_d = \{x \in \mathbb{R}_+^{[d/2]} : x_1 > \dots > x_{[d/2]} > 0\},$$

and its closure

$$\bar{\mathcal{C}}_d = \{x \in \mathbb{R}_+^{[d/2]} : x_1 \geq \dots \geq x_{[d/2]} \geq 0\}.$$

**Definition 6.1.** We define the function  $h_d$  on  $\mathcal{C}_d$  by

$$h_d(\lambda) = c_d(\lambda)^{-1} V_d(\lambda), \quad \lambda \in \mathcal{C}_d,$$

where the functions  $V_d$  and  $c_d$  are given by :

$$\begin{aligned} V_n(\lambda) &= \prod_{1 \leq i < j \leq [d/2]} (\lambda_i - \lambda_j) \prod_{1 \leq i < j \leq [d/2]} (\lambda_i + \lambda_j) \prod_{1 \leq i \leq [d/2]} \lambda_i^\varepsilon, \\ c_n(\lambda) &= \prod_{1 \leq i < j \leq [d/2]} (j - i) \prod_{1 \leq i < j \leq [d/2]} (d - j - i) \prod_{1 \leq i \leq [d/2]} \left(\left[\frac{d}{2}\right] + \frac{1}{2} - i\right)^\varepsilon, \end{aligned}$$

whit  $\varepsilon$  equal to 1 when  $d \notin 2\mathbb{N}$  and 0 otherwise.

Next proposition is an immediate consequence of propositions 4.8 and 5.1 of [3]

**Proposition 6.2.** Let  $(M(n), n \geq 0)$ , be a process on  $i\mathcal{A}_d$  defined by

$$M(n) = \sum_{l=1}^n Y_l \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix} Y_l^*,$$

where the  $Y_l$ 's are independent standard Gaussian variables on  $\mathcal{M}_{d,2}$ . If  $\Lambda(n)$  is the vector of  $\bar{\mathcal{C}}_d$  whose components are the  $[d/2]$  biggest eigenvalues of  $M(n)$ ,  $n \in \mathbb{N}$ , then the process  $(\Lambda(n), n \geq 0)$  is a Markov chain on  $\bar{\mathcal{C}}_d$  with transition probabilities

$$p_d(x, dy) = \frac{h_d(y)}{h_d(x)} m_d(x, y) dy,$$

for  $x, y \in \mathcal{C}_d$ , where  $dy$  is the Lebesgue measure on  $\mathbb{R}_+^{[d/2]}$  and

$$m_d(x, y) = \int_{\mathbb{R}_+^r} \mathbf{1}_{\{z \preceq x, y\}} e^{-\sum_{i=1}^m (y_i + x_i - 2z_i)} dz$$

when  $d = 2r + 1$  and

$$m_d(x, y) = \int_{\mathbb{R}_+^{r-1}} \mathbf{1}_{\{z \preceq |x|, |y|\}} e^{-\sum_{i=1}^{r-1} (x_i + y_i - 2z_i)} (e^{-|x_r - y_r|} + e^{-(x_r + y_r)}) dz$$

when  $d = 2r$ .

## 7. RESULTS

**Theorem 7.1.** *The process  $(X^k(t))_{t \geq 0}$  is a Markov process on  $\mathcal{W}_{k+1}^+$ . If we denote  $R_k$  its transition kernel then*

- $R_1 = R$ .
- when  $k$  is even  $R_k = P_{k+1}$ ,
- when  $k$  is an odd integer greater than 2

$$R_k(x, y) = \begin{cases} P_{k+1}(x, y) + P_{k+1}(x, \tilde{y}) & \text{if } y_{\frac{k+1}{2}} \neq 0 \\ P_{k+1}(x, y) & \text{otherwise,} \end{cases}$$

for  $x, y \in \mathcal{W}_{k+1}^+$ , where  $\tilde{y} = (y_1, \dots, y_{\frac{k-1}{2}}, -y_{\frac{k+1}{2}})$ .

If  $(\Lambda(n), n \geq 0)$  is the process of eigenvalues considered at proposition 6.2 with  $d = k + 1$  then the following theorem holds.

**Theorem 7.2.** *Letting  $q = 1 - \frac{1}{N}$ , the process  $(\frac{X^k(n)}{N}, n \geq 1)$  converges in distribution towards the process of eigenvalues  $(\Lambda(n), n \geq 1)$  as  $N$  goes to infinity.*

**Theorem 7.3.** *Letting  $q = \frac{1}{N}$ , the process  $(X([Nt]), t \geq 0)$  converges in distribution towards the process  $(Y(t), t \geq 0)$  as  $N$  goes to infinity.*

## 8. PROOFS

**Proof of theorem 7.1.** Proof of theorem 7.1 rests on an intertwining property and an application of a Pitman and Rogers criterion given in [6].

**Definition 8.1.** *Let  $\xi_1$  and  $\xi_2$  be two independent geometric random variables. For  $x, a \in \mathbb{N}$  such that  $x \geq a$ , the law of the random variable*

$$\max(a, x - \xi_1),$$

is denote by  $\overset{a \leftarrow}{P}(x, \cdot)$ . For  $x, b \in \mathbb{N}$  such that  $x \leq b$  we denote by  $\overset{\rightarrow b}{P}(x, \cdot)$  and  $\overset{\rightarrow b}{R}(x, \cdot)$  the laws of the random variables

$$\min(b, x + \xi_1) \quad \text{and} \quad \min(b, |x + \xi_1 - \xi_2|).$$

For  $x, y \in \mathbb{R}^2$  such that  $x \leq y$  we let

$$P(x, y) = (1 - q)q^{y-x}.$$

The two following lemmas are proved by straightforward computations.

**Lemma 8.2.** *For  $a, x, y \in \mathbb{N}$  such that  $a \leq y \leq x$*

$$\overset{a \leftarrow}{P}(x, y) = \begin{cases} (1 - q)q^{x-y} & \text{if } a + 1 \leq y \\ q^{x-a} & \text{if } y = a. \end{cases}$$

For  $b, x, y \in \mathbb{N}$  such that  $b \geq y \geq x$

$$\overset{\rightarrow b}{P}(x, y) = \begin{cases} (1 - q)q^{y-x} & \text{if } y \leq b - 1 \\ q^{b-x} & \text{if } y = b. \end{cases}$$

For  $b, x, y \in \mathbb{N}$  such that  $b \geq y, x$

$$\overset{\rightarrow b}{R}(x, y) = \begin{cases} \frac{1-q}{1+q}(q^{|y-x|} + q^{x+y}) & \text{if } y \leq b-1, y > 0 \\ \frac{1-q}{1+q}q^x & \text{if } y \leq b-1, y = 0 \\ \frac{1}{1+q}q^b(q^{-x} + q^x) & \text{if } y = b, y > 0 \\ 1 & \text{if } y = b, y = 0. \end{cases}$$

**Lemma 8.3.** For  $(x, y, z) \in \mathbb{N}^3$  such that  $0 < z \leq y$

$$(3) \quad \sum_{u=0}^z (1_{u=0} + 2 \mathbf{1}_{u>0}) R(u, x) \overset{u \leftarrow}{P}(y, z) = (1-q)(1_{x=0} + 2 \mathbf{1}_{x>0}) q^{x \vee z + y - 2z}$$

For  $(x, y, a) \in \mathbb{N}^3$  such that  $a \leq y$  and  $y \leq x$

$$(4) \quad \sum_{u=a}^y q^u \overset{u \leftarrow}{P}(x, y) = q^{x-y} q^a$$

For  $(x, y, a) \in \mathbb{N}^3$  such that  $y \leq a$  and  $x \leq y$

$$(5) \quad \sum_{v=y}^a q^{-v} \overset{\rightarrow v}{P}(x, y) = q^{y-x} q^{-a}$$

For  $y \in \mathbb{N}, y' \in \mathbb{N}^*$  such that  $y' \leq a$

$$(6) \quad \sum_{v=y'}^a q^{v \vee y - 2v} \overset{\rightarrow v}{R}(y \wedge v, y') = \frac{1}{1-q} q^{-a} R(y, y')$$

We first prove theorem 7.1 for  $k = 2$ . Consider the set

$$\mathcal{W}_{2,3}^+ = \{(z, y) \in \mathbb{N}^2 : z \leq y\}.$$

Define a Markov kernel  $S_2$  on  $\mathcal{W}_{2,3}^+$  letting

$$S_2((z_0, y_0), (z, y)) = \begin{cases} (1-q)^2 \frac{s_2(y)}{s_2(y_0)} q^{y_0 + y - 2z} \mathbf{1}_{z \leq y_0 \wedge y} & \text{if } z > 0 \\ \frac{(1-q)^2}{1+q} \frac{s_2(y)}{s_2(y_0)} q^{y_0 + y} & \text{if } z = 0. \end{cases}$$

for  $(z_0, y_0), (z, y) \in \mathcal{W}_{2,3}^+$  and another one  $L_2$  from  $\mathcal{W}_{2,3}^+$  to  $\mathbb{N} \times \mathcal{W}_{2,3}^+$  letting

$$L_2((z_0, y_0), (x, z, y)) = (1_{x=0} + 2 \mathbf{1}_{x>0}) \frac{1}{s_2(y)} \mathbf{1}_{x \leq y} \mathbf{1}_{(z_0, y_0) = (z, y)},$$

for  $(z_0, y_0), (z, y) \in \mathcal{W}_{2,3}^+$  and  $x \in \mathbb{N}$ . The fact that  $S_2$  is a Markov kernels follows from proposition 5.2 with  $d = 3$ . The process

$$(X_1^1(n), X_1^2(n - \frac{1}{2}), X_1^2(n))_{n \geq 1},$$

is clearly Markovian. Its transition kernel is denoted by  $Q_2$ . Then  $Q_2, L_2$  and  $S_2$  satisfy the following intertwining.

**Lemma 8.4.**

$$L_2 Q_2 = S_2 L_2.$$

*Proof.* For  $(x, z, y), (x', z', y') \in \mathbb{N} \times \mathcal{W}_{2,3}^+$  such that  $x \leq y$  and  $x' \leq y'$

$$Q_2((x, z, y), (x', z', y')) = R(x, x') \overset{x \leftarrow}{P}(y, z') P(x' \vee z', y').$$

Thus

$$L_2 Q_2((z, y), (x', z', y')) = \sum_{x=0}^{z'} \frac{s_1(x)}{s_2(y)} R(x, x') \overset{x \leftarrow}{P}(y, z') P(x' \vee z', y')$$

As  $L_2$ ,  $S_2$  and  $Q_2$  are Markov kernels it is sufficient to prove the identity for  $z' > 0$ . In that case identity (3) of lemma 8.3 implies that

$$\sum_{x=0}^{z'} \frac{(1_{x=0} + 2 \mathbf{1}_{x>0})}{s_2(y)} R(x, x') \overset{x \leftarrow}{P}(y, z') = (1-q)(1_{x'=0} + 2 \mathbf{1}_{x'>0}) q^{x' \vee z' + y - 2z'}.$$

Thus

$$L_2 Q_2((z, y), (x', z', y')) = \frac{(1_{x'=0} + 2 \mathbf{1}_{x'>0})}{s_2(y)} (1-q)^2 q^{y+y'-2z'},$$

which proves that

$$L_2 Q_2 = S_2 L_2.$$

□

**Proposition 8.5.** *Letting  $X_1^2(-\frac{1}{2}) = X_1^2(1) = 0$ , the process*

$$(X_1^2(n - \frac{1}{2}), X_1^2(n))_{n \geq 0}$$

*is a Markov process on  $\mathcal{W}_{2,3}^+$  with transition probability  $S_2$ .*

*Proof.* Since the process

$$(X_1^1(n), X_1^2(n - \frac{1}{2}), X_1^2(n))_{n \geq 1}$$

is Markovian with transition kernel  $Q_2$ , proposition follows from the intertwining property of lemma 8.4 and the criterion of Pitman and Rogers given in [6]. □

Theorem 7.1 follows when  $k = 2$  from proposition 8.5. For the general case one defines the process  $(Z^k(n), Y^k(n))_{n \geq 1}$ , letting

$$\begin{aligned} Z^k(n) &= (X_1^k(n - \frac{1}{2}), \dots, X_{[\frac{k}{2}]}^k(n - \frac{1}{2})), \\ Y^k(n) &= X^k(n), \end{aligned}$$

for  $n \geq 1$  and  $Z^k(0) = Y^k(0) = 0$ . Let us notice that  $Z^k$  is equal to  $X^k$  when  $k$  is even, whereas it is obtained from  $X^k$  by deleting its smallest component when  $k$  is odd. We consider the subset  $\mathcal{W}_{k,k+1}^+$  of  $\mathcal{W}_k^+ \times \mathcal{W}_{k+1}^+$  defined by

$$\mathcal{W}_{k,k+1}^+ = \{(z, y) \in \mathcal{W}_k^+ \times \mathcal{W}_{k+1}^+ : z \preceq y\},$$

and a Markov kernel  $S_k$  on  $\mathcal{W}_{k,k+1}^+$  letting for every  $(z, y), (z', y') \in \mathcal{W}_{k,k+1}^+$

$$(7) \quad S_k((z, y), (z', y')) = (1-q)^k \frac{s_k(y')}{s_k(y)} q^{\sum_{i=1}^r (y_i + y'_i - 2z_i)} (1_{z_r > 0} + \frac{1_{z_r = 0}}{1+q}) 1_{z' \preceq y, y'}$$

when  $k = 2r$ , and

$$(8) \quad S_k((z, y), (z', y')) = (1-q)^{k-1} \frac{s_k(y')}{s_k(y)} R(y_r, y'_r) q^{\sum_{i=1}^{r-1} (y_i + y'_i - 2z_i)} 1_{z' \preceq y, y'}$$

when  $k = 2r - 1$ . The fact that for  $(z, y) \in \mathcal{W}_{k, k+1}^+$  the measure  $S_k((z, y), \cdot)$  is a probability measure is a consequence of proposition 5.2 when  $d = k + 1$ .

**Notation.** Since for  $(z, y) \in \mathcal{W}_{k, k+1}^+$  the probability  $S_k((z, y), \cdot)$  doesn't depend on  $z$  it will be denoted by  $S_k(y, \cdot)$  when there is no ambiguity.

**Lemma 8.6.** *If the process*

$$(Z^{k-1}(n), Y^{k-1}(n))_{n \geq 1},$$

*is a Markov process on  $\mathcal{W}_{k-1, k}^+$  with transition kernel  $S_{k-1}$  then the process*

$$(Y^{k-1}(n), Z^k(n), Y^k(n))_{n \geq 1}$$

*is a Markov process on the set*

$$\{(x, (z, y)) \in \mathcal{W}_k^+ \times \mathcal{W}_{k, k+1}^+ : x \preceq y\}.$$

*If we denote its transition kernel by  $Q_k$  then for  $(u, z, y), (x, z', y') \in \mathcal{W}_k^+ \times \mathcal{W}_{k, k+1}^+$  such that  $u \preceq y$  and  $x \preceq y'$*

$$(9) \quad \begin{aligned} Q_k((u, z, y), (x, z', y')) &= \sum_{v \in \mathbb{N}^{r-1}} S_{k-1}(u, (v, x)) \overset{\rightarrow v_{r-1}}{R}(y_r \wedge v_{r-1}, y'_r) \\ &\quad \times \prod_{i=1}^{r-1} \overset{u_i \leftarrow}{P}(y_i \wedge v_{i-1}, z'_i) \prod_{i=1}^r \overset{\rightarrow v_{i-1}}{P}(z'_i \vee x_i, y'_i), \end{aligned}$$

*when  $k = 2r - 1$  and*

$$(10) \quad \begin{aligned} Q_k((u, z, y), (x, z', y')) &= \sum_{v \in \mathbb{N}^{r-1}} S_{k-1}(u, (v, x)) \overset{u_r \leftarrow}{P}(y_r \wedge v_{r-1}, z'_r) \\ &\quad \times \prod_{i=1}^{r-1} \overset{u_i \leftarrow}{P}(y_i \wedge v_{i-1}, z'_i) \prod_{i=1}^r \overset{\rightarrow v_{i-1}}{P}(z'_i \vee x_i, y'_i), \end{aligned}$$

*when  $k = 2r$ . In the odd and the even cases  $v_0 = +\infty$  and the sum runs over  $v = (v_1, \dots, v_{r-1}) \in \mathbb{N}^{r-1}$  such that  $v_i \in \{y'_{i+1}, \dots, x_i \wedge z'_i\}$ , for  $i \in \{1, \dots, r-1\}$*

*Proof.* The dynamic of the model implies that the process

$$(Z^{k-1}(n), Y^{k-1}(n), Z^k(n), Y^k(n), n \geq 0)$$

is Markovian. Since for  $(z, y) \in \mathcal{W}_{k-1, k}^+$  the transition probability  $S_{k-1}((z, y), \cdot)$  doesn't depend on  $z$ , the Markovianity of the process

$$(Y^{k-1}(n), Z^k(n), Y^k(n), n \geq 0)$$

follows. Identities (9) and (10) is deduced from the blocking and pushing interactions.  $\square$

Let us define Markov Kernel  $L_k$  from  $\mathcal{W}_{k, k+1}^+$  to  $\mathcal{W}_k^+ \times \mathcal{W}_{k, k+1}^+$  letting for  $x \in \mathcal{W}_k^+$  and  $(z, y), (z_0, y_0) \in \mathcal{W}_{k, k+1}^+$

$$(11) \quad L_k((z_0, y_0), (x, y, z)) = 1_{(z_0, y_0) = (z, y)} \frac{s_{k-1}(x)}{s_k(y)} 1_{x \preceq y},$$

when  $k$  is odd and

$$(12) \quad L_k((z_0, y_0), (x, y, z)) = (1_{\{0\}}(x_{\frac{k}{2}}) + 2 1_{\mathbb{N}^*}(x_{\frac{k}{2}})) 1_{(z_0, y_0) = (z, y)} \frac{s_{k-1}(x)}{s_k(y)} 1_{x \preceq y},$$

when  $k$  is even. The following proposition generalizes lemma 8.4.

**Proposition 8.7.** *Markov kernels  $S_k$ ,  $L_k$  and  $Q_k$  defined as in (7), (8), (11), (12) and lemma 8.6 satisfy the intertwining*

$$L_k Q_k = S_k L_k.$$

*Proof.* For  $(z, y) \in \mathcal{W}_{k,k+1}^+$ ,  $(x, z', y') \in \mathcal{W}_k^+ \times \mathcal{W}_{k,k+1}^+$  such that  $x \preceq y'$ ,

$$L_k Q_k((z, y), (x, z', y')) = \sum_{u \in \mathcal{W}_k^+} L_k((z, y), (u, z, y)) Q_k((u, z, y), (x, z', y')).$$

We prove separately the even and the odd cases. When  $k = 2r$ , the sum is equal to

$$\begin{aligned} & \sum_{(u,v) \in \mathbb{N}^r \times \mathbb{N}^{r-1}} \frac{s_{k-1}(x)}{s_k(y)} (1_{\{0\}}(u_r) + 2 1_{\mathbb{N}^*}(u_r)) (1-q)^{2r-2} R(u_r, x_r) q^{\sum_{i=1}^{r-1} (x_i + u_i - 2v_i)} \\ & \quad \times P(z'_1 \vee x_1, y'_1) \prod_{i=1}^r \overset{u_i \leftarrow}{P}(y_i \wedge v_{i-1}, z'_i) \prod_{i=2}^r \overset{\rightarrow v_{i-1}}{P}(z'_i \vee x_i, y'_i). \end{aligned}$$

where the sum runs over  $(u, v) \in \mathbb{N}^r \times \mathbb{N}^{r-1}$  such that  $u_r \in \{0, \dots, z'_r\}$ ,  $v_i \in \{y'_{i+1}, \dots, x_i \wedge z'_i\}$ ,  $u_i \in \{v_i \vee y_{i+1}, \dots, z'_i\}$ , for  $i \in \{1, \dots, r-1\}$ . Thus the sum equals

$$\begin{aligned} & \sum_{v \in \mathbb{N}^{r-1}} \frac{s_{k-1}(x)}{s_k(y)} (1-q)^{2r-2} q^{\sum_{i=1}^{r-1} x_i} P(z'_1 \vee x_1, y'_1) \prod_{i=2}^r q^{-2v_{i-1}} \overset{\rightarrow v_{i-1}}{P}(z'_i \vee x_i, y'_i) \\ & \quad \times \sum_{u \in \mathbb{N}^r} (1_{\{0\}}(u_r) + 2 1_{\mathbb{N}^*}(u_r)) (1-q)^{2r-2} R(u_r, x_r) \prod_{i=1}^r q^{u_i} \overset{u_i \leftarrow}{P}(y_i \wedge v_{i-1}, z'_i). \end{aligned}$$

For a fixed  $v$  the sum over  $u$  is

$$\sum_{u_r=0}^{z'_r} (1_{\{0\}}(u_r) + 2 1_{\mathbb{N}^*}(u_r)) R(u_r, x_r) \overset{u_r \leftarrow}{P}(y_r \wedge v_{r-1}, z'_r) \prod_{i=1}^{r-1} \sum_{u_i=v_i \vee y_{i+1}}^{z'_i} q^{u_i} \overset{u_i \leftarrow}{P}(y_i \wedge v_{i-1}, z'_i).$$

Since  $L_k$  and  $Q_k$  are Markov kernels it is sufficient to consider the case when  $z_r > 0$ . In that case, identities (3) and (4) of lemma 8.3 imply that the sum over  $u$  equals

$$(1_{\{0\}}(x_r) + 2 1_{\mathbb{N}^*}(x_r)) q^{x_r \vee z'_r + y_r \wedge v_{r-1} - 2z'_r} (1-q) \prod_{i=1}^{r-1} q^{y_i \wedge v_{i-1} - z'_i + v_i \vee y_{i+1}}.$$

i.e.

$$(1_{\{0\}}(x_r) + 2 1_{\mathbb{N}^*}(x_r)) q^{x_r \vee z'_r + y_r - 2z'_r + \sum_{i=1}^{r-1} y_i + v_i - z'_i} (1-q).$$

Thus

$$L_{2r} Q_{2r}((z, y), (x, z', y'))$$

equals

$$\begin{aligned} & \frac{s_{k-1}(x)}{s_k(y)} (1-q)^{2r-1} (1_{\{0\}}(x_r) + 2 1_{\mathbb{N}^*}(x_r)) q^{x_r \vee z'_r + y_r - 2z'_r + \sum_{i=1}^{r-1} y_i - z'_i} q^{\sum_{i=1}^{r-1} x_i} \\ & \quad \times P(z'_1 \vee x_1, y'_1) \prod_{i=2}^r \sum_{v_{i-1}=y_i}^{x_{i-1} \vee z'_{i-1}} q^{-v_{i-1}} \overset{\rightarrow v_{i-1}}{P}(z'_i \vee x_i, y'_i). \end{aligned}$$

Identity (5) of lemma 8.3 gives that

$$\begin{aligned} \prod_{i=2}^r \sum_{v_{i-1}=y_i}^{x_{i-1} \vee z'_{i-1}} q^{-v_{i-1}} \overset{\rightarrow v_{i-1}}{P}(z'_i \vee x_i, y'_i) &= \prod_{i=2}^r q^{y'_i - z'_i \vee x_i - x_{i-1} \wedge z'_{i-1}} \\ &= q^{y'_r - z'_r \vee x_r - x_1 \wedge z'_1} q^{\sum_{i=2}^{r-1} y'_i - x_i - z'_i}, \end{aligned}$$

which implies

$$L_{2r} Q_{2r}((z, y), (x, z', y')) = \frac{s_{k-1}(x)}{s_k(y)} (1-q)^{2r} (1_{\{0\}}(x_r) + 2 1_{\mathbb{N}^*}(x_r)) q^{\sum_{i=1}^r y_i + y'_i - 2z'_i},$$

and achieves the proof for the even case. Similarly when  $k = 2r - 1$

$$\begin{aligned} L_{2r-1} Q_{2r-1}((z, y), (x, z', y')) &= \sum_{u, v \in \mathbb{N}^{r-1}} \frac{s_{k-1}(x)}{s_k(y)} q^{\sum_{i=1}^{r-1} x_i - 2v_i} \overset{\rightarrow v_{r-1}}{R}(y_k \wedge v_{r-1}, y'_k) \\ &\quad \times \prod_{i=1}^{r-1} q^{u_i} \overset{u_i \leftarrow}{P}(y_i \wedge v_{i-1}, z'_i) \prod_{i=1}^r \overset{\rightarrow v_{i-1}}{P}(z'_i \vee x_i, y'_i), \end{aligned}$$

where the sum runs over  $(u, v) \in \mathbb{N}^{r-1} \times \mathbb{N}^{r-1}$  such that  $v_i \in \{y'_{i+1}, \dots, x_i \wedge z'_i\}$ ,  $u_i \in \{v_i \vee y_{i+1}, \dots, z'_i\}$ , for  $i \in \{1, \dots, r-1\}$ . We obtain the intertwining in a quite similar way as in the even case, using identities (4), (5) and (6) of lemma 8.3.  $\square$

**Proposition 8.8.** *The process  $(Z^k(n), Y^k(n))_{n \geq 1}$ , is Markovian with transition kernel  $S_k$  defined in (8).*

*Proof.* Conditionally to the process  $(X^{k-1}(t), t \geq 0)$  processes  $(X^k(t), t \geq 0)$  and  $(X^l(t), t \geq 0)$ , for  $l = 1, \dots, k-2$ , are independent. So the property can be proved by induction on  $k$ . Proposition 8.5 claims that it is true for  $k = 2$ . Suppose that proposition is true for a fixed interger  $k-1$  greater than 1. Lemma 8.6 implies that the process

$$(Y^{k-1}(n), Z^k(n), Y^k(n))_{n \geq 1}$$

is Markovian with transition kernel  $Q_k$ . The intertwining of proposition 8.7 implies, by using the Pitman and Rogers criterion given in [6], that the process

$$(Z^k(n), Y^k(n))_{n \geq 1}$$

is Markovian with probability  $S_k$ .  $\square$

Theorem 7.1 is an immediate corollary of proposition 8.8.

**Proof of theorem 7.2.** Let  $(x_N)_{N \geq 1}$  be a sequence of elements of  $\mathcal{W}_{k+1}^+$  such that  $\frac{x_N}{N}$  converges to  $x \in \mathcal{C}_{k+1}$  as  $N$  goes to infinity and  $(\nu_N)_{N \geq 1}$  be a sequence of probability measures on  $\mathcal{W}_{k+1}^+$  defined by

$$\nu_N = \sum_{y \in \mathcal{W}_{k+1}^+} R_k(x_N, y) \delta_{\frac{1}{N}y},$$

Propositions 5.2 and 6.2 imply that the measure  $\nu_N$  converges to the measure  $p_{k+1}$  defined in proposition 6.2 as  $N$  goes to infinity. Theorem 7.2 follows.

**Proof of theorem 7.3.** Proof of theorem 7.3 rests on a similar argument as in section 2.7 of [2].

**Lemma 8.9.** *Let  $T_1(q)$  and  $T_2(q)$  be two (possibly infinite) lower and upper triangular matrices, whose matrix coefficients are polynomials in an indeterminate  $q > 0$ :*

$$\begin{cases} T_1(q) = A_0 + qA_1 + q^2A_2 + \dots, \\ T_2(q) = B_0 + qB_1 + q^2B_2 + \dots, \end{cases}$$

and assume that  $A_0 = B_0 = I$ . Then for  $t \in \mathbb{R}_+$ ,

$$\lim_{q \rightarrow 0} (T_1(q)T_2(q))^{[t/q]} = \exp(t(A_1 + B_1)).$$

*Proof.* Because of the triangularity assumption, lemma follows, as in the proof of lemma 2.21 of [2], from the claim for finite size matrices which is standard.  $\square$

Theorem 7.3 follows immediately from the last lemma taking

$$\begin{cases} T_1(q)(x, y) = \mathbb{P}(X(n + \frac{1}{2}) = y | X(n) = x), \\ T_2(q)(x, y) = \mathbb{P}(X(n + 1) = y | X(n + \frac{1}{2}) = x), \end{cases}$$

for  $x, y \in GT_k$ .
