(Dated: November 23, 2010)

We calculate the cross sections and final state distributions for the processes $e^+e^- \to \Upsilon(1S)(\pi^+\pi^-, K^+K^-, \eta\pi^0)$ near the $\Upsilon(5S)$ resonance based on the tetraquark hypothesis. This framework is used to analyse the available data on the $\Upsilon(1S)\pi^+\pi^-$ and $\Upsilon(1S)K^+K^-$ final states [K. F. Chen *et al.* (Belle Collaboration), Phys. Rev. Lett. **100**, 112001 (2008); I. Adachi *et al.* (Belle Collaboration), arXiv:0808.2445], yielding good fits. Dimeson invariant mass spectra in these processes are shown to be dominated by the corresponding light scalar and tensor states. The resulting correlations among the cross sections are worked out. We also predict $\sigma(e^+e^- \to \Upsilon(1S)K^+K^-)/\sigma(e^+e^- \to \Upsilon(1S)K^0\bar{K}^0) = 1/4$, reflecting the electric charges of the underlying diquarks. These features provide crucial tests of the tetraquark framework and can be searched for in the currently available and forthcoming data from the B factories.

PACS numbers: 14.40.Rt, 14.40.Pq, 13.66.Bc

The anomalously large production cross sections for $e^+e^- \to \Upsilon(1S)\pi^+\pi^-, \Upsilon(2S)\pi^+\pi^-$ and $e^+e^- \to \Upsilon(3S)\pi^+\pi^-$ measured between $\sqrt{s} = 10.83$ GeV and 11.02 GeV by the Belle Collaboration [1, 2] at KEK do not agree well with the lineshape and production rates for the conventional $b\bar{b}$ state $\Upsilon(10860)$ (also called $\Upsilon(5S)$). A fit to the measured production cross sections using a Breit-Wigner resonance shape yielded a peak mass of $[10888.4^{+2.7}_{-2.6}(\text{stat}) \pm 1.2(\text{syst})]$ MeV and a width of $[30.7^{+8.3}_{-7.0}(\text{stat}) \pm 3.1(\text{syst})]$ MeV for the observed state, henceforth called $Y_b(10890)$ [2]. More data are required to understand the resonance structure in this region. In [3], a dynamical model was developed to explain the Belle data for the final states $\Upsilon(1S)\pi^+\pi^-$ and $\Upsilon(2S)\pi^+\pi^-$ in terms of the production and decays of the states $Y_{[b,l/h]}$, which are linear superposition of the $J^{PC} = 1^{--}$ hidden $b\bar{b}$ tetraquark states $Y_{[bu]} \equiv [bu][\bar{b}\bar{u}]$ and $Y_{[bd]} \equiv [bd][\bar{b}\bar{d}]$. The mass difference, estimated as $M(Y_{[b,h]}) - M(Y_{[b,l]}) = (5.6 \pm 2.8)$ MeV [4, 5], was ignored and the mass-degenerate states $Y_{[b,l]}$ and $Y_{[b,h]}$ were identified with the $Y_b(10890)$. This model described the distributions in the dipion invariant mass and the helicity angle measured by Belle [1] well and offered an explanation of the rates in terms of the Zweig-allowed transitions $Y_{[b,l/h]} \to (\Upsilon(1S), \Upsilon(2S), \Upsilon(3S))\pi^+\pi^-$. While credible, the interpretation of $Y_b(10890)$ in terms of the $b\bar{b}$ tetraquark states $Y_{[b,l]}$ and $Y_{[b,h]}$ requires further experimental scrutiny. It is the aim of this Letter to provide some definitive tests to confirm or rule out the tetraquark interpretation of the Belle data.

To that end, we further develop the tetraquark formalism for the processes

$$e^+ + e^- \to Y_b(q) \to \Upsilon(1S)(p) + P(k_1) + P'(k_2), \quad (1)$$

where PP' stands for the pseudoscalar-meson pairs $\pi^+\pi^-$, K^+K^- and $\eta\pi^0$, and q, p, k_1 and k_2 are the momenta of Y_b, $\Upsilon(1S)$, P and P', respectively. We ne-

glect other background processes, based on prior data on the dipionic transitions involving higher $\Upsilon(nS)$ to lower $\Upsilon(mS)$ $(m < n)$ states [6]. Following [7], the low mass scalar 0^{++} hadrons σ or $f_0(600)$, $f_0(980)$ and $a_0^0(980)$ (the upper index indicates the $I_3 = 0$ component of the iso-triplet a_0), which enter as intermediate states in the processes $Y_b \to \Upsilon(1S) + [\sigma, f_0(980), \cdots] \to \Upsilon(1S)PP'$, are assumed to be tetraquark states. These intermediate $J^{PC} = 0^{++}$ states together with the $J^{PC} = 2^{++}$ state $f_2(1270)$ provide the dominant resonating part of the amplitudes for the processes considered in this work. These resonances are labeled σ, f_0, a_0^0 and f_2 henceforth. We determine the coupling constants involving these light tetraquark states and the mesons PP' from the known decays from the PDG [6] and data from the E791 [8], the BES [9], the Crystal Barrel (CB) [10] and the KLOE Collaborations [11, 12], adopting the Flatté model [13] for the σ, f_0 and a_0^0 couplings to take into account threshold effects. The non-resonating continuum contributions are parameterized in terms of two *a priori* unknown constants [14]. With this formalism, we analyze the invariant-mass $M_{PP'}$ and the $\cos\theta$ spectra, where $M_{PP'} = (k_1 + k_2)^2$ and θ is the angle between the momenta of Y_b and P in the PP' rest frame.

The theoretical framework described here provides good fits of the Belle data on the invariant dipion mass spectrum and $\cos\theta$ distribution in the process $e^+e^- \to \Upsilon(1S)\pi^+\pi^-$ and the ratio $\sigma_{\Upsilon(1S)K^+K^-}/\sigma_{\Upsilon(1S)\pi^+\pi^-}$, with $\sigma_{\Upsilon(1S)PP'}$ being the cross section $\sigma(e^+e^- \to \Upsilon(1S)PP')$. We present the invariant mass distributions for the K^+K^- and $\eta\pi^0$ mesons in the processes $e^+e^- \to \Upsilon(1S)(K^+K^-, \eta\pi^0)$, which are dominated by the respective $J^{PC} = 0^{++}$ resonances. The resulting correlations among $\sigma_{\Upsilon(1S)\pi^+\pi^-}$, $\sigma_{\Upsilon(1S)K^+K^-}$ and $\sigma_{\Upsilon(1S)\eta\pi^0}$ are worked out. Constraining these correlations from the existing data on the first two processes, we predict $\sigma_{\Upsilon(1S)\eta\pi^0}/\sigma_{\Upsilon(1S)\pi^+\pi^-}$. We also pre-

dict $\sigma_{\Upsilon(1S)K^+K^-}/\sigma_{\Upsilon(1S)K^0\bar{K}^0} = 1/4$, reflecting the ratio $Q^2_{[bu]}/Q^2_{[bd]}$ with $Q_{[bu]} = 1/3$ and $Q_{[bd]} = -2/3$ being the effective electric charges for the constituent diquarks of $Y_{[bu]}$ and $Y_{[bd]}$, respectively.

We start by defining the tetraquark states in the isospin basis, with the two isospin components $Y_b^0 \equiv (Y_{[bu]} + Y_{[bd]})/\sqrt{2}$ and $Y_b^1 \equiv (Y_{[bu]} - Y_{[bd]})/\sqrt{2}$ for isospin $I = 0$ and $I = 1$, respectively. The two mass eigenstates $Y_{[b,l]}$ and $Y_{[b,h]}$ are identified with $Y_{[bu]}$ and $Y_{[bd]}$, as the mixings between them is small. We ignore the mass difference and also the isospin breaking effects except for the production processes $e^+e^- \to Y_b^I$ hereafter.

We calculate the decay amplitude as a sum of the Breit-Wigner resonances and non-resonating continuum contributions, with the latter adopted from [14]. The differential cross section is then written as

$$\frac{d^2\sigma_{\Upsilon(1S)PP'}}{dM_{PP'}\,d\cos\theta} = \frac{\lambda^{1/2}(s, m_\Upsilon^2, M_{PP'}^2)\lambda^{1/2}(M_{PP'}^2, m_P^2, m_{P'}^2)}{384\pi^3 s\, M_{PP'}\left[(s - m_{Y_b}^2)^2 + m_{Y_b}^2\Gamma_{Y_b}^2\right]}$$

$$\times \left\{ \left(1 + \frac{(q\cdot p)^2}{2s\,m_\Upsilon^2}\right)|\mathcal{S}|^2 \right.$$

$$+ 2\,\mathrm{Re}\left[\mathcal{S}^*\left(\mathcal{D}' + \frac{(q\cdot p)^2}{2s\,m_\Upsilon^2}\mathcal{D}''\right)\right]\left(\cos^2\theta - \frac{1}{3}\right)$$

$$+ |\mathcal{D}|^2\sin^2\theta\left[\sin^2\theta + 2\left(\frac{(q^0)^2}{s} + \frac{(p^0)^2}{m_\Upsilon^2}\right)\cos^2\theta\right]$$

$$\left. + \left(|\mathcal{D}'|^2 + \frac{(q\cdot p)^2}{2s\,m_\Upsilon^2}|\mathcal{D}''|^2\right)\left(\cos^2\theta - \frac{1}{3}\right)^2 \right\}, \quad (2)$$

where $\lambda(x, y, z) \equiv (x - y - z)^2 - 4yz$, q^0 and p^0 are the energies of the Y_b and $\Upsilon(1S)$ in the PP' rest frame, respectively, Γ_{Y_b} is the decay width of Y_b, and m_{Y_b}, m_Υ, m_P and $m_{P'}$ are the masses of Y_b, $\Upsilon(1S)$, P and P', respectively. We take $m_{Y_b} = 10.89$ GeV and $\Gamma_{Y_b} = 30$ MeV in the numerical analysis below. A detailed derivation of the above formula will be presented in [15].

Each PP' channel receives specified contributions depending on the isospin of PP' and the kinematically allowed region for the invariant mass $M_{PP'} \in [m_P + m_{P'}, \sqrt{s} - m_{\Upsilon(1S)}]$. The S-wave amplitude for the PP' system, $\mathcal{S}$, and the D-wave amplitudes, $\mathcal{D}$, $\mathcal{D}'$ and $\mathcal{D}''$, are the sums over possible isospin states

$$\mathcal{M} = \sum_I \mathcal{M}_I \quad \text{for} \quad \mathcal{M} = \mathcal{S},\ \mathcal{D},\ \mathcal{D}',\ \mathcal{D}'', \quad (3)$$

where $I = 0$ for $\pi^+\pi^-$, $I = 0, 1$ for K^+K^-, and $I = 1$ for $\eta\pi^0$, since the $\Upsilon(1S)$ is an isospin 0 state, and the following resonances contribute to each process:

$$\begin{array}{ll} \sigma,\ f_0 \text{ and } f_2 & \text{for } \pi^+\pi^-, \\ f_0,\ a_0^0 \text{ and } f_2 & \text{for } K^+K^-, \\ a_0^0 & \text{for } \eta\pi^0. \end{array} \quad (4)$$

The $I = 0$ amplitudes are given by the combinations of the resonance amplitudes, $\mathcal{M}_0^S$ and $\mathcal{M}_0^{f_2}$, and the non-resonating continuum amplitudes, $\mathcal{M}_0^{1C}$ and $\mathcal{M}_0^{2C}$:

$$\mathcal{S}_0 = \mathcal{M}_0^{1C} + (k_1\cdot k_2)\sum_S \mathcal{M}_0^S, \quad \mathcal{D}_0 = |\boldsymbol{k}|^2\mathcal{M}_0^{f_2},$$

$$\mathcal{D}_0' = \mathcal{M}_0^{2C} - \mathcal{D}_0, \quad \mathcal{D}_0'' = \mathcal{M}_0^{2C} + \frac{2q^0p^0}{(q\cdot p)}\mathcal{D}_0, \quad (5)$$

where S runs over possible $I = 0$ scalar resonances in Eq. (4), and $|\boldsymbol{k}|$ is the magnitude of the three momentum of $P^{(')}$ in the PP' rest frame. Similarly, the $I = 1$ amplitudes are given by

$$\mathcal{S}_1 = \frac{g_{e^+e^- - Y_b^1}}{g_{e^+e^- - Y_b^0}}\left[\mathcal{M}_1^{1C} + (k_1\cdot k_2)\mathcal{M}_1^{a_0^0}\right],$$

$$\mathcal{D}_1 = 0, \quad \mathcal{D}_1' = \mathcal{D}_1'' = \frac{g_{e^+e^- - Y_b^1}}{g_{e^+e^- - Y_b^0}}\mathcal{M}_1^{2C}, \quad (6)$$

where the dimensionless couplings $g_{e^+e^- - Y_b^0}$ and $g_{e^+e^- - Y_b^1}$ are defined via the Lagrangian

$$\mathcal{L} = g_{e^+e^- - Y_b^0}Y_{b\mu}^0\,(\bar{e}\gamma^\mu e) + g_{e^+e^- - Y_b^1}Y_{b\mu}^1\,(\bar{e}\gamma^\mu e). \quad (7)$$

The ratio $g_{e^+e^- - Y_b^1}/g_{e^+e^- - Y_b^0}$ is determined by the effective diquark charges of the isospin eigenstates: $g_{e^+e^- - Y_b^1}/g_{e^+e^- - Y_b^0} = (Q_{[bu]} - Q_{[bd]})/(Q_{[bu]} + Q_{[bd]}) = -3$.

To calculate the production cross sections, we derive the corresponding Van Royen-Weisskopf formula for the leptonic decay widths of the tetraquark states made up of point-like diquarks:

$$\Gamma(Y_{[bu/bd]} \to e^+e^-) = \frac{24\alpha^2|Q_{[bu/bd]}|^2}{m_{Y_b}^4}\kappa^2\left|R_{11}^{(1)}(0)\right|^2, \quad (8)$$

where α is the fine-structure constant, the parameter κ takes into account differing sizes of the tetraquarks compared to the standard bottomonia, with $\kappa < 1$ anticipated, and $|R_{11}^{(1)}(0)|^2 = 2.067$ GeV^5 [16] is the square of the derivative of the radial wave function for $\chi_b(1P)$ taken at the origin. Hence, the leptonic widths of the tetraquark states are estimated as

$$\Gamma(Y_{[bd]} \to e^+e^-) = 4\,\Gamma(Y_{[bu]} \to e^+e^-) \approx 83\,\kappa^2 \text{ eV}, \quad (9)$$

which are substantially smaller than the leptonic width of the $\Upsilon(5S)$ [6]. Since the couplings in Eq. (7) are related to the leptonic widths as

$$\Gamma(Y_{[bu/bd]} \to e^+e^-) = \frac{m_{Y_b}}{24\pi}|g_{e^+e^- - Y_b^0} \pm g_{e^+e^- - Y_b^1}|^2, \quad (10)$$

we obtain $|g_{e^+e^- - Y_b^0}| \approx 2\times 10^{-4}\kappa$ from Eq. (9). Combining the knowledge of the production process and the measured cross section for $e^+e^- \to \Upsilon(1S)\pi^+\pi^-$, we estimate $\Gamma(Y_{[bu/bd]} \to \Upsilon(1S)\pi^+\pi^-)$ to be $O(1)$ MeV.

The continuum amplitudes in Eq. (5) are written in terms of the two form factors A and B [14, 15] as

$$\mathcal{M}_0^{1C} = \frac{2A}{f_P f_{P'}}(k_1\cdot k_2) + \frac{B}{f_P f_{P'}}\frac{3(q^0)^2 k_1^0 k_2^0 - |\boldsymbol{q}|^2|\boldsymbol{k}|^2}{3s},$$

$$\mathcal{M}_0^{2C} = -\frac{B}{f_P f_{P'}}\frac{|\boldsymbol{q}|^2|\boldsymbol{k}|^2}{s}, \quad (11)$$

where $f_{P^{(\prime)}}$ is the decay constant of $P^{(\prime)}$, and $|\boldsymbol{q}|$, k_1^0 and k_2^0 are the magnitude of the three momentum of Y_b and the energies of P and P' in the PP' rest frame, respectively. Using SU(3) symmetry, we assume the relations $\mathcal{M}_0^{1C,2C}(\Upsilon(1S)K^+K^-) = (\sqrt{3}/2)\,\mathcal{M}_0^{1C,2C}(\Upsilon(1S)\pi^+\pi^-)$, $\mathcal{M}_1^{1C,2C}(\Upsilon(1S)K^+K^-) = \mathcal{M}_0^{1C,2C}(\Upsilon(1S)K^+K^-)$ and $\mathcal{M}_1^{1C,2C}(\Upsilon(1S)\eta\pi^0) = \sqrt{2}\,\mathcal{M}_1^{1C,2C}(\Upsilon(1S)K^+K^-)$.

The resonant contributions are expressed by the Breit-Wigner formula:

$$\mathcal{M}_I^R = \frac{g_{RPP'}\,g_{Y_b^I\Upsilon(1S)R}\,g_{e^+e^- Y_b^0}}{M_{PP'}^2 - m_R^2 + i\,m_R\Gamma_R}\,e^{i\varphi_R}, \qquad (12)$$

where $I = 0$ for $R = \sigma$, f_0 and f_2, and $I = 1$ for $R = a_0^0$. The couplings for the scalar resonances S are defined through the Lagrangian

$$\mathcal{L} = g_{SPP'}(\partial_\mu P)(\partial^\mu P')\,S + g_{Y_b\Upsilon(1S)S}\,Y_{b\mu}\Upsilon^\mu S, \quad (13)$$

while those for the f_2 meson are defined through

$$\mathcal{L} = 2g_{f_2PP'}(\partial_\mu P)(\partial_\nu P')f_2^{\mu\nu} + g_{Y_b\Upsilon(1S)f_2}Y_{b\mu}\Upsilon_\nu f_2^{\mu\nu}. \; (14)$$

The couplings $g_{RPP'}$ and $g_{Y_b^I\Upsilon(1S)R}$ have mass dimensions -1 and 1, respectively. For the σ, f_0 and a_0^0, we adopt the Flatté model [13]

$$m_\sigma\Gamma_\sigma = f_{\sigma\pi\pi}^2\rho_{\pi\pi}, \quad m_{f_0}\Gamma_{f_0} = f_{f_0\pi\pi}^2\rho_{\pi\pi} + f_{f_0K\bar{K}}^2\rho_{K\bar{K}},$$
$$m_{a_0^0}\Gamma_{a_0^0} = f_{a_0^0\eta\pi}^2\rho_{\eta\pi} + f_{a_0^0K\bar{K}}^2\rho_{K\bar{K}} \qquad (15)$$

with the phase space factor

$$\rho_{ab} = \left[\left(1 - \frac{(m_a - m_b)^2}{M_{PP'}^2}\right)\left(1 - \frac{(m_a + m_b)^2}{M_{PP'}^2}\right)\right]^{1/2}, \; (16)$$

where the Flatté couplings $f_{SPP'}$ are related to the vertex couplings $g_{SPP'}$ entering in Eq. (12) via

$$g_{SPP'}(k_1 \cdot k_2) = 4\sqrt{\pi}\,f_{SPP'}. \qquad (17)$$

The couplings in Eq. (17) are defined for an exclusive final state. Summing over final states, e.g., $f_{f_0\pi\pi}^2 = f_{f_0\pi^+\pi^-}^2 + f_{f_0\pi^0\pi^0}^2$, we obtain the isospin relations $f_{S\pi\pi} = \sqrt{3/2}\,f_{S\pi^+\pi^-}$, $f_{SK\bar{K}} = \sqrt{2}\,f_{SK^+K^-}$ and $f_{S\eta\pi} = f_{S\eta\pi^0}$. For the σ meson, we extract the coupling $g_{\sigma\pi^+\pi^-}$ from the E791 data [8]: $g_{\sigma\pi^+\pi^-} = 26.7$ GeV^{-1} with $m_\sigma = 478$ MeV, yielding the Flatté coupling $f_{\sigma\pi\pi} = 437$ MeV. For the f_0 and a_0^0 mesons, we adopt the masses and the Flatté couplings measured by the BES [9] and CB [10] Collaborations (the corresponding couplings from KLOE [11, 12] are shown in the parentheses):

$$m_{f_0} = 965(984),\; f_{f_0\pi\pi} = 406(349),\; f_{f_0K\bar{K}} = 833(869),$$
$$m_{a_0^0} = 982(983),\; f_{a_0^0\eta\pi} = 324(398),\; f_{a_0^0K\bar{K}} = 329(429)\; (18)$$

FIG. 1. Fit results (a) of the $M_{\pi^+\pi^-}$ distribution and (b) of the $\cos\theta$ distribution for $e^+e^- \to Y_b \to \Upsilon(1S)\pi^+\pi^-$, normalized by the measured cross section. The histograms (green bars) represent the fit results, while the crosses are the Belle data [1]. The resonant contributions from the σ and $f_0(980)$ (left red curve) and the $f_2(1270)$ (right black curve) are also indicated in (a).

TABLE I. Best fit parameters, yielding χ^2/d.o.f. $= 21.6/15$, where A' and B' are dimensionless, $g'_{Y_b^0\Upsilon(1S)f_0}$ and $g'_{Y_b^0\Upsilon(1S)f_2}$ are given in units of MeV, and the angles are in units of rad.

A'	B'	$g'_{Y_b^0\Upsilon(1S)f_0}$	$g'_{Y_b^0\Upsilon(1S)f_2}$	φ_σ	φ_{f_0}	φ_{f_2}
0.000081	-0.00020	0.320	0.432	0.38	-2.68	-0.31

in units of MeV. Furthermore, we extract the couplings for the f_2 meson through the formula

$$\Gamma(f_2 \to PP') = \frac{g_{f_2PP'}^2 m_{f_2}^3}{480\pi}\left(1 - \frac{4m_P^2}{m_{f_2}^2}\right)^{5/2} \qquad (19)$$

for $m_P = m_{P'}$, where the data for $\Gamma(f_2 \to \pi\pi) = (3/2)\,\Gamma(f_2 \to \pi^+\pi^-)$ and $\Gamma(f_2 \to K\bar{K}) = 2\,\Gamma(f_2 \to K^+K^-)$, and $m_{f_2} = 1275$ MeV are taken from PDG [6]. The other inputs for the pseudo-scalar mesons and the $\Upsilon(1S)$ are also taken from PDG.

Having detailed our dynamical model, we now perform a simultaneous fit to the binned $\Upsilon(1S)\pi^+\pi^-$ data for the $M_{\pi^+\pi^-}$ and $\cos\theta$ distributions measured by Belle at $\sqrt{s} = 10.87$ GeV [1], normalizing them by the measured cross section: $d\tilde{\sigma}_{\pi^+\pi^-}/dM_{\pi\pi}$ and $d\tilde{\sigma}_{\pi^+\pi^-}/d\cos\theta$, where $\tilde{\sigma}_{\pi^+\pi^-} \equiv \sigma_{\Upsilon(1S)\pi^+\pi^-}/\sigma_{\Upsilon(1S)\pi^+\pi^-}^{\text{Belle}}$ with $\sigma_{\Upsilon(1S)\pi^+\pi^-}^{\text{Belle}} = 1.61 \pm 0.16$ pb [1]. With SU(3) symmetry for the $Y_b^0\Upsilon(1S)R$ couplings entering in Eq. (12), i.e., setting $g_{Y_b^0\Upsilon(1S)\sigma} = g_{Y_b^0\Upsilon(1S)f_0}$, we have 7 free parameters:

$$A',\; B',\; g'_{Y_b^0\Upsilon(1S)f_0},\; g'_{Y_b^0\Upsilon(1S)f_2},\; \varphi_\sigma,\; \varphi_{f_0},\; \varphi_{f_2}, \quad (20)$$

where the first four primed parameters are rescaled as $A' \equiv A|g_{e^+e^- Y_b^0}|$ and so forth. Hence the number of degree of freedom (d.o.f.) in the fit is $(12 + 10) - 7 = 15$. To make predictions for the $\Upsilon(1S)K^+K^-$ and $\Upsilon(1S)\eta\pi^0$ modes, we assume SU(3) for the couplings and the phases, i.e., $g_{Y_b^0\Upsilon(1S)f_0} = g_{Y_b^1\Upsilon(1S)a_0^0}$ and $\varphi_{f_0} = \varphi_{a_0^0}$. We also assume that there is no phase difference between the two continuum amplitudes $\mathcal{M}_0^{1C,2C}$ and $\mathcal{M}_1^{1C,2C}$.

With these inputs, we have performed a large number of fits (typically $O(5000)$) of the Belle data with the tetraquark theory predictions. The resultant best fit is
FIG. 2. Predictions (a) of the $M_{K^+K^-}$ distribution for $e^+e^- \to Y_b \to \Upsilon(1S)K^+K^-$, (b) of the $M_{\eta\pi^0}$ distribution for $e^+e^- \to Y_b \to \Upsilon(1S)\eta\pi^0$ and (c) of the correlation between the cross sections of $\Upsilon(1S)K^+K^-$ and $\Upsilon(1S)\eta\pi^0$, normalized by the measured cross section for the $\Upsilon(1S)\pi^+\pi^-$ mode. In (a) and (b), the dotted (solid) curves show the dimeson invariant mass spectra from the resonant (total) contribution. In (c), the red dots represent predictions from our fit solutions satisfying $\chi^2/\text{d.o.f.} < 1.6$. The shaded (green) band shows the current Belle measurement $\widetilde{\sigma}_{K^+K^-} = 0.11^{+0.04}_{-0.03}$ [1].

fairly good, with $\chi^2/\text{d.o.f.} = 21.6/15$ for the BES and CB input in Eq. (18), which corresponds to a p-value of 0.12. The corresponding best fit using the KLOE data is very similar, having a $\chi^2/\text{d.o.f.} = 21.9/15$, yielding a p-value of 0.11. The best fit using the BES and CB data is presented in Fig. 1 and the corresponding fit values of the parameters are listed in Table I. Further details about the correlations among the parameters and the cross sections will be presented in a forthcoming paper [15]. Concluding the discussion of the final state $\Upsilon(1S)\pi^+\pi^-$, we note that the resonance contribution represented by the left red curve (S-wave from σ and f_0) and the right black curve (D-wave from f_2) in Fig. 1 (a) dominate the $M_{\pi^+\pi^-}$ spectrum, supporting our dynamical model in the decay $Y_b \to \Upsilon(1S)\pi^+\pi^-$. Sufficient data may provide enough statistics to undertake an analysis in the end-region of $M_{\pi^+\pi^-}$ to probe the angular distribution of $f_2 \to \pi^+\pi^-$.

The normalized $M_{K^+K^-}$ and $M_{\eta\pi^0}$ distributions, calculated with the best-fit parameters in Table I, are shown in Fig. 2 (a) and Fig. 2 (b), respectively. In these figures, the dotted (solid) curves show the dimeson invariant mass spectra from the resonant (total) contribution. Since these spectra are dominated by the scalars $f_0 + a_0^0$ and a_0^0, respectively, there is a strong correlation between the two cross sections. This is shown in Fig. 2 (c), where we have plotted the normalized cross sections $\widetilde{\sigma}_{K^+K^-}$ and $\widetilde{\sigma}_{\eta\pi^0}$ resulting from our fits (dotted points) which all satisfy $\chi^2/\text{d.o.f.} < 1.6$. The current Belle measurement $\widetilde{\sigma}_{K^+K^-} = 0.11^{+0.04}_{-0.03}$ [1] is shown as a shaded (green) band on this figure. Our model is in agreement with the Belle measurement, though there is a tendency in the fits to yield larger value for $\widetilde{\sigma}_{K^+K^-}$. Our predictions will be further tested as and when the cross section $\widetilde{\sigma}_{\eta\pi^0}$ is measured. Noticing that we have neglected the SU(3)-breaking effects, we predict $1.0 \lesssim \widetilde{\sigma}_{\eta\pi^0} \lesssim 2.0$.

Finally, we note that the states $\Upsilon(1S)K^+K^-$ and $\Upsilon(1S)K^0\bar{K}^0$ are produced by the underlying mechanism $e^+e^- \to Y_{[bu]} \to \Upsilon(1S)K^+K^-$ and $e^+e^- \to Y_{[bd]} \to \Upsilon(1S)K^0\bar{K}^0$. Hence, a firm prediction is

$$\frac{\sigma_{\Upsilon(1S)K^+K^-}}{\sigma_{\Upsilon(1S)K^0\bar{K}^0}} = \frac{Q_{[bu]}^2}{Q_{[bd]}^2} = \frac{1}{4}. \qquad (21)$$

This relation is valid under the assumption that the diquarks are point-like. In terms of the mass eigenstates, we predict $\sigma_{\Upsilon(1S)K^+K^-} = \sigma_{\Upsilon(1S)K_S K_S}$.

The distributions, cross sections, and correlations presented here are crucial tests of the underlying tetraquark hypothesis in the $b\bar{b}$ sector and go well beyond what has been proposed in the literature to understand the nature of the $Y_b(10890)$ state [3]. They will be scrutinized soon in the existing and the forthcoming Belle data to which we look forward.
