## ABSTRACT

The susceptibility of different regions in *Dioscorea rotundata* (white yam) tuber to rot infecting fungi was investigated. Isolation was made from the periphery of the rotted tuber tissues, followed by a pathogenicity test and identification of isolates. Three fungi associated with *D. rotundata* (white yam) were isolated; they include *Penicillium oxalicum*, *Aspergillus niger* and *Rhizopus stolonifer*. Each of the isolates from pure cultures were inoculated on the head, middle and tail regions of healthy yam tubers. The three fungi were found to be pathogenic at different rates at the head, middle and tail ends of the yam tuber respectively. The head region was less susceptible to the three fungi with the following rot depths (*P. oxalicum* 25 mm<sup>a</sup>, *A. niger* 18.2 mm<sup>a</sup> and *R. stolonifer* 12.7 mm<sup>b</sup>). Rot depth in the middle region was (*P. oxalicum* 15 mm<sup>a</sup>, *A. niger* 10.6 mm<sup>a</sup> and *R. stolonifer* 8.8 mm<sup>b</sup>). While the tail region of the yam tuber recorded rot depth of (*P. oxalicum* 32.0 mm<sup>a</sup>, *A. niger* 26.4 mm<sup>a</sup> and *R. stolonifer* 20.8 mm<sup>b</sup>) respectively. Generally, the tail region of *D. rotundata* was more susceptible to fungal attack and the rot recorded in the tail region was significantly different from rot at the middle and the head. It was recommended that yam tubers should be stacked with their head on the ground to reduce incidence of rotting in stock-piled yam tubers.

**Keywords:** *Dioscorea rotundata*; Tuber; Fungal Dry Rot; Head; Middle; Tail

## 1. Introduction

The word “yam” refers to the tuber of the botanical genus *Dioscorea* in the family *Dioscoreaceae* [1]. In Nigeria, Adamawa, Taraba, Benue, Nassarawa, Kogi, Edo and Kaduna states are the major yam producing states. Edible species of yam include *D. rotundata* Pour, *D. cayenensis* Lam; *D. insipida* Dennst; *D. bulbifera* L.; *D. opposeta* Thumb; and *D. trifida* Lare [2].

Nigeria, cultivates three edible species namely: *D. rotundata* Pour (white yam), *D. cayenensis* Lam (yellow yam) and *D. bulbifera* L. (Aerial yam); together with three other species namely: *D. alata* L (water yam), *D. esculenta* (Lour) Burk (Chinese yam) and *D. dumetorum* Pax (Cluster yam) [3].

*Dioscorea rotundata* is a swollen tuber, a liana, which contain about eighteen different amino acids in smaller quantities and mainly carbohydrates [4], a fact that makes it a major source of carbohydrate for most people in the world, especially Africans and Asians. The yam tuber could be prepared into a number of forms; it could be boiled and pounded into “fufu”, porridge, roasted or mashed. In the Niger-Delta of Nigeria, it is cooked into a delicacy known as “ukodo” (yam and pepper soup) that is usually used for marriage and burial ceremonies or as breakfast, particularly during the cold season. It could

also be processed into flour. It can also be fried into chips or flakes, which are excellent food for most people [5]. Cultivation of *D. rotundata* has offered employment to farmers and traders in the region. Its subsistent production level augments the incomes of most families. The yam peelings also form part of household waste use in feeding livestock [6].

Idah local government area in Kogi State is one of the major producers of white yam in Nigeria. The area lies along the coast of Rivers Niger and Benue; with a total rainfall of about 1500 mm per annum and a characteristic clayey-loamy soil which avail the yam a good environment to thrive.

The occurrence of a large number of *D. rotundata* cultivars in eastern Nigerian [7], lends support to the belief that *D. rotundata* is native to Nigeria; with most probable place of origin as the eastern bank of the River Niger where it is still the preferred food crop [8,9]. In this region, yam is not only an important staple food; it is considered a man’s crop. It has rituals and socio-cultural significance; it is the food of choice at many ceremonies and festivals, and an indispensable part of bride price [8]. New yam festivals are celebrated annually, during the months of August and September, in eastern Nigeria.

The white yam (*D. rotundata*) is produced in large

quantities and often stored for use later. Unfortunately, considerable amount of the tubers get rotted during storage. Post-harvest losses of yams alone account for about 7 million tonnes out of the world's total production of 27.08 million tonnes [10].

In Nigeria, post-harvest bio-deterioration of yam tubers resulting in microbe-induced rot is one of the most important factors militating against commercial production of yam [11].

The problems associated with yam tuber start from the field. During harvest, most of the tubers are bruised or damaged, thereby predisposing them to microbial attack that could cause rot during storage. Each year, appreciable tonnes of harvested tubers are lost to microbial attack, especially fungi and bacteria [12].

Microbial infection has been reported to be rapid and severe where temperature and relative humidity favours their growth and enzyme production [13]. Considerable number of yam farmers has shown that fungal attack on yam occurs through injuries on the tuber [14]. A freshly injured yam rapidly loses moisture from the injured area leaving the injured site dry and become impervious to the hyphae of growing fungi; but the development of the protective coat on the injured site takes time. It is within the time of formation of this impervious coat that airborne spores of rot-causing fungi settle and grow on such injuries.

Many fungi have been identified by various workers as causal organisms of various yam diseases. [12,15-17] isolated *Colletotrichum gloeosporioides* as a fungal pathogen infecting minisettes through infested tubers. *Botryodiplodia theobromae*, *Aspergillus niger*, *A. tamarii*, *Cladosporium herbarum*, *Cylindrocapsa radicola*, *Gleocladium roseum*, *Geotrichum candidum*, *Gliomatrixconvulata*, *Macrophomina phaseoli*, *Mucor circinelloides*, *Fusarium moniliforme*, *F. solani*, *Penicillium cyclopium*, *P. sclerotigenum*, *Rhizoctonia solani*, *Rhizopus nigricans*, *R. stolonifer*, and *Rosellina* spp. are other fungal pathogens associated with rots of yam tubers [18].

This research is aimed at identifying the various fungi associated with dry rot of *D. rotundata* in the area, and to determine the portion of the tuber that is more susceptible to fungal attack.

## 2. Materials and Methods

Rotted and clean yam tubers (*D. rotundata*) were purchased from Idah market, washed under running tap water and allowed to dry, observed under a binocular for possible dry rot signs, before about 0.5 - 1 cm pieces were cut at the periphery of the rotted tissues with the aid of sterile scalpel. Potato Dextrose Agar (PDA) was the medium used. Fresh potatoes were peeled, washed before 250 g were weighed and boiled for 30 minutes in 1 litre of tap water in a clean pot. The infusion was filtered and

allowed to cool. To the infusion, 20 g of agar-agar and 15 g of dextrose were added. The infusion was made up to 1 litre with distilled water before the medium was autoclaved at 1.02 kg/cm<sup>3</sup> pressure for 15 minutes. Six millilitre (0.1%) of streptomycin was added to the 1 litre of the sterilized media just, before pouring into Petri-dishes, to prevent the growth of bacteria.

The cut pieces were plated two per Petri-dish and incubated at room temperature for five days after sterilization in 2% sodium hypochlorite for 30 seconds and rinsed in three changes of sterile water. Pure culture of each isolate was maintained by aseptic transfer to a freshly prepared medium. Wet mount of isolate in lactophenol in cotton blue were microscopically examined and identified on the basis of characteristic spores with reference to illustrated general of imperfect fungi [19] Pathogenicity test of each fungi isolate was carried out based on Koch's postulate using the method described by [20].

Susceptibility of yam regions to fungal attack was carried out by taking cylindrical cores of 1cm deep aseptically from the "head", "middle" and "tail" regions of each yam tuber with a 5 mm cork-borer. Four millimeter disc of 7 days old fungal cultures were placed, fungus first into the holes in the tubers, before the cores of the yam from the tubers were replaced after about 2 mm have been cut off to compensate for the thickness of the Agar inoculums. Petroleum Jelly was used to cover the replaced cores to prevent contamination. Each experiment for the tuber regions was replicated three times. Controls were inoculated with plank sterile agar and all inoculated tubers were incubated at room temperature for four weeks; after which they were sliced through the site of inoculation and rot depth measured.

## 3. Results and Discussion

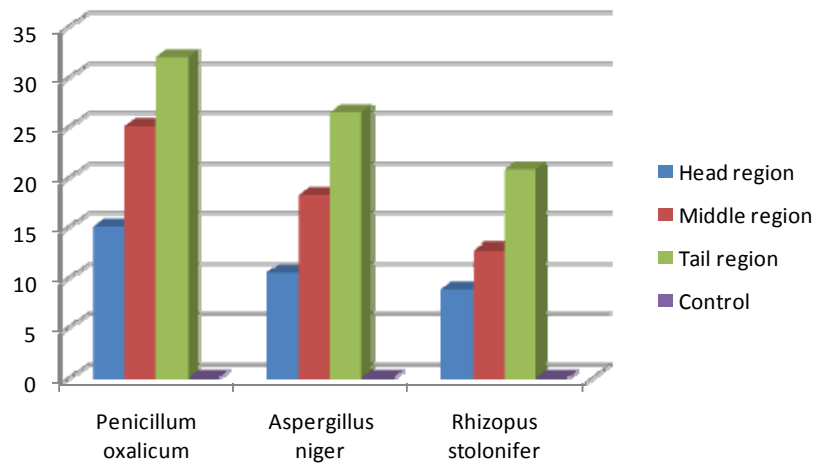

Various workers have identified many fungi as causal organisms of various yam diseases [17,21-24]. In this research, three fungal pathogens (*P. oxalicum*, *A. niger* and *R. stolonifer*) were isolated and identified from rotted white yam (*D. rotundata*) in Idah Local Government Area in Kogi State. These fungi were pathogenic and they were responsible for the dry rot of yam in the area (**Table 1**).

Fungal dry rot of yam tuber in storage in Idah LGA (one of the major yam producing area in Kogi State) has led to loss of yam quality and quantity and consequently financial loss to farmers in the area. This confirmed the earlier reports by [25,26]; that post-harvest biodegradation of yam tuber is one of the most important factors militating against commercial production of yams in Nigeria.

**Table 1. The results of the susceptibility test.**

Fungi	Rot depth average in mm			
	Head region	Middle region	Tail region	Control
<i>Penicillium oxalicum</i>	15.0 <sup>a</sup>	25.0 <sup>a</sup>	32.0 <sup>a</sup>	-
<i>Aspergillus niger</i>	10.5 <sup>a</sup>	18.2 <sup>a</sup>	26.4 <sup>a</sup>	-
<i>Rhizopus stolonifer</i>	8.8 <sup>b</sup>	12.7 <sup>b</sup>	20.8 <sup>b</sup>	-

**Figure 1. Rate of dry rot in *Dioscorea rotundata* (white yam) along the tuber length due to rot causing fungi.**

shows no significant level (Duncan's multiple range test).

The tail region of the yam tubers showed higher susceptibility to the fungal pathogens (32.0 mm, 26.4 mm and 20.8 mm) for *P. oxalicum*, *A. niger* and *R. stolonifer* respectively; these results were significantly different from the result gotten from the middle and the head regions. Although the susceptibility of the middle region was less than that of the tail region, by the three fungi isolates (25.0 mm, 18.2 mm and 12.7 mm) for *P. oxalicum*, *A. niger* and *R. stolonifer* respectively; and this result was still higher from those observed at the head region (15.0 mm, 10.5 mm and 8.8 mm) for *P. oxalicum*, *A. niger* and *R. stolonifer* respectively; however, but there was no difference in susceptibility of the middle and that at the head regions (**Figure 1**).

Based on the observation from this research, farmers and traders are advised to take precautions during stacking of yam tubers in ware-houses not to stand them on the tail region as this could provide an easier way of exposing the tubers to injury and consequent rapid infection.
